Algorithmic graph structure theory

Dániel Marx$^1$

$^1$Institute for Computer Science and Control, Hungarian Academy of Sciences (MTA SZTAKI) Budapest, Hungary

14th Max Planck Advanced Course on the Foundations of Computer Science (ADFOCS 2013) August 5–9, 2013 Saarbrücken, Germany
Classes of graphs can be described by

1. what they do not have, (excluded structures)
2. how they look like (constructions and decompositions).

In general, the second description is more useful for algorithmic purposes.
Classes of graphs

**Example:** Trees
1. Do not contain cycles (and connected)
2. Have a tree structure.

**Example:** Bipartite graphs
1. Do not contain odd cycles,
2. Edges going only between two classes.

**Example:** Chordal graphs
1. Do not contain induced cycles,
2. Clique-tree decomposition and simplicial ordering.
“Graph structure theory” usually refers to the theory developed by Robertson and Seymour on graphs excluding minors.

**Definition**

Graph $H$ is a **minor** of $G$ ($H \leq G$) if $H$ can be obtained from $G$ by deleting edges, deleting vertices, and contracting edges.
Excluding minors

**Theorem [Wagner 1937]**

A graph is a planar if and only if it excludes $K_5$ and $K_{3,3}$ as a minor.
Excluding minors

Theorem [Wagner 1937]

A graph is a planar if and only if it excludes $K_5$ and $K_{3,3}$ as a minor.

- How do graphs excluding $H$ (or $H_1, \ldots, H_k$) look like?
- What other classes can be defined this way?

The work of Robertson and Seymour gives some kind of combinatorial answer to that and provides tools for the related algorithmic questions.
Minor closed properties

**Definition**

A set $G$ of graphs is **minor closed** if $G \in G$ and $H \leq G$ implies $H \in G$.

**Examples of minor closed properties:**

- planar graphs
- graphs that can be drawn on the torus
- acyclic graphs (forests)
- graphs having no cycle longer than $k$
- empty graphs

**Examples of not minor closed properties:**

- complete graphs
- regular graphs
- bipartite graphs
Wagner’s conjecture

Let \( G \) be a minor closed class of graphs. Then \( G \) can be characterized by the minimal obstructions:

Let \( H \in \mathcal{F} \) if \( H \not\in G \), but every proper minor of \( H \) is in \( G \).

\[
G \in \mathcal{G} \iff \forall H \in \mathcal{F}, H \not\succeq G
\]
Wagner’s conjecture

Let $G$ be a minor closed class of graphs. Then $G$ can be characterized by the minimal obstructions:

Let $H \in \mathcal{F}$ if $H \notin G$, but every proper minor of $H$ is in $G$.

$$G \in G \iff \forall H \in \mathcal{F}, H \not\subseteq G$$

**Theorem [Robertson and Seymour]**

Every class $G$ closed under taking minors has a finite set $\mathcal{F}$ of minimal obstructions.
Graph Minors Theorem

Well-quasi-ordering:

**Theorem** [Robertson and Seymour]

Every class $G$ closed under taking minors has a finite set $\mathcal{F}$ of minimal obstructions.

Minor testing:

**Theorem** [Robertson and Seymour]

For every fixed graph $H$, there is an $O(n^3)$ time algorithm for testing whether $H$ is a minor of the given graph $G$.

**Corollary:** For every minor closed property $G$, there is an $O(n^3)$ time algorithm for testing whether a given graph $G$ is in $G$. 
Graph Minors results

- The proof spans around 400 pages in the paper series “Graph Minors I–XXIII”.
- The size of the obstruction sets and the constants in the algorithms can be astronomical even for simple properties.
The proof spans around 400 pages in the paper series “Graph Minors I–XXIII”.

The size of the obstruction sets and the constants in the algorithms can be astronomical even for simple properties.

Why should you know about this theory?

- The theory introduces simpler concepts and techniques that are useful on their own in many contexts.
- Some of the more complicated results can be formulated as self-contained powerful statements that can be used as a black box.
Graph Minors Theorem

- Treewidth
- Grid theorems
- Planar graphs

- Structure theorem

- Minor testing

- Well-quasi-ordering
Fixed-parameter tractability

Main definition

A parameterized problem is **fixed-parameter tractable (FPT)** if there is an $f(k)n^c$ time algorithm for some constant $c$.

Main goal of parameterized complexity: to find FPT problems.

Examples of NP-hard problems that are FPT:
- Finding a vertex cover of size $k$.
- Finding a path of length $k$.
- Finding $k$ disjoint triangles.
- Drawing the graph in the plane with $k$ edge crossings.
- Finding disjoint paths that connect $k$ pairs of points.
...
Fixed-parameter tractability

**Main definition**

A parameterized problem is **fixed-parameter tractable (FPT)** if there is an \( f(k)n^c \) time algorithm for some constant \( c \).

Main goal of parameterized complexity: to find FPT problems.

Examples of NP-hard problems that are FPT:

- Finding a vertex cover of size \( k \).
- Finding a path of length \( k \).
- Finding \( k \) disjoint triangles.
- Drawing the graph in the plane with \( k \) edge crossings.
- Finding disjoint paths that connect \( k \) pairs of points.
- \ldots
Downey and Fellows started the systematic investigation of fixed-parameter tractability and its hardness theory in the 80s.

$n^f(k)$ vs. $f(k) \cdot n^c$.

Many of the algorithmic results from graph structure theory can be formulated and appreciated using the language of fixed-parameter tractability.

The original motivation of Downey and Fellows comes from graph structure theory!

**The Party Problem**

**Party Problem**

**Problem:** Invite some colleagues for a party.

**Maximize:** The total fun factor of the invited people.

**Constraint:** Everyone should be having fun.

---

**Graph**

A tree with weights on the vertices.

**Task:** Find an independent set of maximum weight.
The Party Problem

**PARTY PROBLEM**

**Problem:** Invite some colleagues for a party.

**Maximize:** The total fun factor of the invited people.

**Constraint:** Everyone should be having fun.

Do not invite a colleague and his direct boss at the same time!

Input: A tree with weights on the vertices.

Task: Find an independent set of maximum weight.
The Party Problem

**Party Problem**

**Problem:** Invite some colleagues for a party.

**Maximize:** The total fun factor of the invited people.

**Constraint:** Everyone should be having fun.

Do not invite a colleague and his direct boss at the same time!

---

**Input:** A tree with weights on the vertices.

**Task:** Find an independent set of maximum weight.
The Party Problem

**Party Problem**

**Problem:** Invite some colleagues for a party.

**Maximize:** The total fun factor of the invited people.

**Constraint:** Everyone should be having fun.

Do not invite a colleague and his direct boss at the same time!

**Input:** A tree with weights on the vertices.

**Task:** Find an independent set of maximum weight.
Solving the Party Problem

Dynamic programming paradigm:
We solve a large number of subproblems that depend on each other. The answer is a single subproblem.

Subproblems:
- $T_v$: the subtree rooted at $v$.
- $A[v]$: max. weight of an independent set in $T_v$
- $B[v]$: max. weight of an independent set in $T_v$ that does not contain $v$

Solving the Party Problem

Subproblems:
- $T_v$: the subtree rooted at $v$
- $A[v]$: max. weight of an independent set in $T_v$
- $B[v]$: max. weight of an independent set in $T_v$ that does not contain $v$

Recurrence:
Assume $v_1, \ldots, v_k$ are the children of $v$. Use the recurrence relations

\[
B[v] = \sum_{i=1}^{k} A[v_i]
\]
\[
A[v] = \max\{B[v], w(v) + \sum_{i=1}^{k} B[v_i]\}
\]

The values $A[v]$ and $B[v]$ can be calculated in a bottom-up order (the leaves are trivial).
Treewidth
Generalizing trees

How could we define that a graph is “treelike”?

**Treewidth — a measure of “tree-likeness”**

**Tree decomposition:** Vertices are arranged in a tree structure satisfying the following properties:

1. If \( u \) and \( v \) are neighbors, then there is a bag containing both of them.
2. For every \( v \), the bags containing \( v \) form a connected subtree.

![Graph and Tree Decomposition Diagram]
Treewidth — a measure of “tree-likeness”

**Tree decomposition:** Vertices are arranged in a tree structure satisfying the following properties:

1. If $u$ and $v$ are neighbors, then there is a bag containing both of them.
2. For every $v$, the bags containing $v$ form a connected subtree.

![Diagram of tree decomposition](image)
Treewidth — a measure of “tree-likeness”

Tree decomposition: Vertices are arranged in a tree structure satisfying the following properties:

1. If $u$ and $v$ are neighbors, then there is a bag containing both of them.
2. For every $v$, the bags containing $v$ form a connected subtree.
Treewidth — a measure of “tree-likeness”

**Tree decomposition:** Vertices are arranged in a tree structure satisfying the following properties:

1. If $u$ and $v$ are neighbors, then there is a bag containing both of them.
2. For every $v$, the bags containing $v$ form a connected subtree.

**Width of the decomposition:** largest bag size $-1$.

**Treewidth:** width of the best decomposition.
Treewidth — a measure of “tree-likeness”

**Tree decomposition:** Vertices are arranged in a tree structure satisfying the following properties:

1. If \( u \) and \( v \) are neighbors, then there is a bag containing both of them.
2. For every \( v \), the bags containing \( v \) form a connected subtree.

**Width of the decomposition:** largest bag size \(-1\).

**treewidth:** width of the best decomposition.

Each bag is a separator.
Treewidth — a measure of “tree-likeness”

Tree decomposition: Vertices are arranged in a tree structure satisfying the following properties:

1. If $u$ and $v$ are neighbors, then there is a bag containing both of them.
2. For every $v$, the bags containing $v$ form a connected subtree.

Width of the decomposition: largest bag size $-1$.

treewidth: width of the best decomposition.

A subtree communicates with the outside world only via the root of the subtree.
Fact: treewidth $= 1 \iff$ graph is a forest

Exercise: A cycle cannot have a tree decomposition of width 1.
Treewidth — outline

1. Basic algorithms
2. Combinatorial properties
3. Applications
Finding tree decompositions

**Hardness:**

**Theorem** [Arnborg, Corneil, Proskurowski 1987]

It is NP-hard to determine the treewidth of a graph (given a graph $G$ and an integer $w$, decide if the treewidth of $G$ is at most $w$).

**Fixed-parameter tractability:**

**Theorem** [Bodlaender 1996]

There is a $2^{O(w^3)} \cdot n$ time algorithm that finds a tree decomposition of width $w$ (if exists).

**Consequence:**

If we want an FPT algorithm parameterized by treewidth $w$ of the input graph, then we can assume that a tree decomposition of width $w$ is available.
Finding tree decompositions — approximately

Sometimes we can get better dependence on treewidth using approximation.

**FPT approximation:**

**Theorem** [Robertson and Seymour]

There is a $O(3^{3w} \cdot w \cdot n^2)$ time algorithm that finds a tree decomposition of width $4w + 1$, if the treewidth of the graph is at most $w$.

**Polynomial-time approximation:**

**Theorem** [Feige, Hajiaghayi, Lee 2008]

There is a polynomial-time algorithm that finds a tree decomposition of width $O(w \sqrt{\log w})$, if the treewidth of the graph is at most $w$. 
Weighted Max Independent Set and treewidth

Theorem

Given a tree decomposition of width $w$, Weighted Max Independent Set can be solved in time $O(2^w \cdot w^{O(1)} \cdot n)$.

$B_x$: vertices appearing in node $x$.

$V_x$: vertices appearing in the subtree rooted at $x$.

Generalizing our solution for trees:

Instead of computing 2 values $A[v], B[v]$ for each vertex of the graph, we compute $2^{|B_x|} \leq 2^{w+1}$ values for each bag $B_x$.

$M[x, S]$: the max. weight of an independent set $I \subseteq V_x$ with $I \cap B_x = S$. 
**Weighted Max Independent Set** and treewidth

**Theorem**

Given a tree decomposition of width \( w \), **Weighted Max Independent Set** can be solved in time \( O(2^w \cdot w^{O(1)} \cdot n) \).

- \( B_x \): vertices appearing in node \( x \).
- \( V_x \): vertices appearing in the subtree rooted at \( x \).

Generalizing our solution for trees:

Instead of computing 2 values \( A[v], B[v] \) for each vertex of the graph, we compute \( 2^{|B_x|} \leq 2^{w+1} \) values for each bag \( B_x \).

\[ M[x, S] : \]

the max. weight of an independent set \( I \subseteq V_x \) with \( I \cap B_x = S \).

How to determine \( M[x, S] \) if all the values are known for the children of \( x \)?
Nice tree decompositions

**Definition**

A rooted tree decomposition is **nice** if every node $x$ is one of the following 4 types:

- **Leaf**: no children, $|B_x| = 1$
- **Introduce**: 1 child $y$ with $B_x = B_y \cup \{v\}$ for some vertex $v$
- **Forget**: 1 child $y$ with $B_x = B_y \setminus \{v\}$ for some vertex $v$
- **Join**: 2 children $y_1, y_2$ with $B_x = B_{y_1} = B_{y_2}$
Nice tree decompositions

Definition
A rooted tree decomposition is nice if every node $x$ is one of the following 4 types:

- **Leaf**: no children, $|B_x| = 1$
- **Introduce**: 1 child $y$ with $B_x = B_y \cup \{v\}$ for some vertex $v$
- **Forget**: 1 child $y$ with $B_x = B_y \setminus \{v\}$ for some vertex $v$
- **Join**: 2 children $y_1, y_2$ with $B_x = B_{y_1} = B_{y_2}$

Theorem
A tree decomposition of width $w$ and $n$ nodes can be turned into a nice tree decomposition of width $w$ and $O(wn)$ nodes in time $O(w^2n)$. 

Weighted Max Independent Set
and nice tree decompositions

- **Leaf:** no children, $|B_x| = 1$
  Trivial!
- **Introduce:** 1 child $y$ with $B_x = B_y \cup \{v\}$ for some vertex $v$

$$m[x, S] = \begin{cases} 
  m[y, S] & \text{if } v \not\in S, \\
  m[y, S \setminus \{v\}] + w(v) & \text{if } v \in S \text{ but } v \text{ has no neighbor in } S, \\
  -\infty & \text{if } S \text{ contains } v \text{ and its neighbor.}
\end{cases}$$

---

![Diagram](image_url)
**Weighted Max Independent Set**
and nice tree decompositions

- **Forget:** 1 child $y$ with $B_x = B_y \setminus \{v\}$ for some vertex $v$

\[
m[x, S] = \max\{m[y, S], m[y, S \cup \{v\}]\}
\]

- **Join:** 2 children $y_1, y_2$ with $B_x = B_{y_1} = B_{y_2}$

\[
m[x, S] = m[y_1, S] + m[y_2, S] - w(S)
\]
Weighted Max Independent Set

and nice tree decompositions

- **Forget:** 1 child \( y \) with \( B_x = B_y \setminus \{ v \} \) for some vertex \( v \)

  \[
m[x, S] = \max\{m[y, S], m[y, S \cup \{v\}]\}
\]

- **Join:** 2 children \( y_1, y_2 \) with \( B_x = B_{y_1} = B_{y_2} \)

  \[
m[x, S] = m[y_1, S] + m[y_2, S] - w(S)
\]

There are at most \( 2^{w+1} \cdot n \) subproblems \( m[x, S] \) and each subproblem can be solved in \( w^{O(1)} \) time (assuming the children are already solved).

\[\downarrow\]

Running time is \( O(2^w \cdot w^{O(1)} \cdot n)\).
Theorem

Given a tree decomposition of width $w$, 3-Coloring can be solved in $O(3^w \cdot w^{O(1)} \cdot n)$.

$B_x$: vertices appearing in node $x$.
$V_x$: vertices appearing in the subtree rooted at $x$.

For every node $x$ and coloring $c : B_x \rightarrow \{1, 2, 3\}$, we compute the Boolean value $E[x, c]$, which is true if and only if $c$ can be extended to a proper 3-coloring of $V_x$. 
3-Coloring and tree decompositions

Theorem

Given a tree decomposition of width \( w \), 3-Coloring can be solved in \( O(3^w \cdot w^{O(1)} \cdot n) \).

\( B_x \): vertices appearing in node \( x \).
\( V_x \): vertices appearing in the subtree rooted at \( x \).

For every node \( x \) and coloring \( c : B_x \rightarrow \{1, 2, 3\} \), we compute the Boolean value \( E[x, c] \), which is true if and only if \( c \) can be extended to a proper 3-coloring of \( V_x \).

How to determine \( E[x, c] \) if all the values are known for the children of \( x \)?
3-Coloring and nice tree decompositions

- **Leaf**: no children, $|B_x| = 1$
  Trivial!

- **Introduce**: 1 child $y$ with $B_x = B_y \cup \{v\}$ for some vertex $v$
  If $c(v) \neq c(u)$ for every neighbor $u$ of $v$, then
  $E[x, c] = E[y, c']$, where $c'$ is $c$ restricted to $B_y$.

- **Forget**: 1 child $y$ with $B_x = B_y \setminus \{v\}$ for some vertex $v$
  $E[x, c]$ is true if $E[y, c']$ is true for one of the 3 extensions of $c$
  to $B_y$.

- **Join**: 2 children $y_1$, $y_2$ with $B_x = B_{y_1} = B_{y_2}$
  $E[x, c] = E[y_1, c] \land E[y_2, c]$
3-Coloring and nice tree decompositions

- **Leaf**: no children, $|B_x| = 1$
  Trivial!

- **Introduce**: 1 child $y$ with $B_x = B_y \cup \{v\}$ for some vertex $v$
  If $c(v) \neq c(u)$ for every neighbor $u$ of $v$, then
  $E[x, c] = E[y, c']$, where $c'$ is $c$ restricted to $B_y$.

- **Forget**: 1 child $y$ with $B_x = B_y \setminus \{v\}$ for some vertex $v$
  $E[x, c]$ is true if $E[y, c']$ is true for one of the 3 extensions of $c$ to $B_y$.

- **Join**: 2 children $y_1, y_2$ with $B_x = B_{y_1} = B_{y_2}$
  $E[x, c] = E[y_1, c] \land E[y_2, c]$

There are at most $3^{w+1} \cdot n$ subproblems $E[x, c]$ and each subproblem can be solved in $w^{O(1)}$ time (assuming the children are already solved).

⇒ Running time is $O(3^w \cdot w^{O(1)} \cdot n)$.

⇒ 3-Coloring is FPT parameterized by treewidth.
Monadic Second Order Logic

**Extended Monadic Second Order Logic (EMSO)**

A logical language on graphs consisting of the following:
- Logical connectives $\land$, $\lor$, $\rightarrow$, $\neg$, $=$, $\neq$
- Quantifiers $\forall$, $\exists$ over vertex/edge variables
- Predicate $\text{adj}(u, v)$: vertices $u$ and $v$ are adjacent
- Predicate $\text{inc}(e, v)$: edge $e$ is incident to vertex $v$
- Quantifiers $\forall$, $\exists$ over vertex/edge set variables
- $\in$, $\subseteq$ for vertex/edge sets

**Example:**
The formula
\[
\exists C \subseteq V \exists v_0 \in C \forall v \in C \exists u_1, u_2 \in C (u_1 \neq u_2 \land \text{adj}(u_1, v) \land \text{adj}(u_2, v))
\]
is true on graph $G$ if and only if . . .
Monadic Second Order Logic

Extended Monadic Second Order Logic (EMSO)

A logical language on graphs consisting of the following:

- Logical connectives $\land$, $\lor$, $\rightarrow$, $\neg$, $=$, $\neq$
- Quantifiers $\forall$, $\exists$ over vertex/edge variables
- Predicate $\text{adj}(u, v)$: vertices $u$ and $v$ are adjacent
- Predicate $\text{inc}(e, v)$: edge $e$ is incident to vertex $v$
- Quantifiers $\forall$, $\exists$ over vertex/edge set variables
- $\in$, $\subseteq$ for vertex/edge sets

Example:
The formula

$$\exists C \subseteq V \exists v_0 \in C \forall v \in C \exists u_1, u_2 \in C(u_1 \neq u_2 \land \text{adj}(u_1, v) \land \text{adj}(u_2, v))$$

is true on graph $G$ if and only if $G$ has a cycle.
Courcelle’s Theorem

If a graph property can be expressed in EMSO, then for every fixed $w \geq 1$, there is a linear-time algorithm for testing this property on graphs having treewidth at most $w$.

**Note:** The constant depending on $w$ can be very large (double, triple exponential etc.), therefore a direct dynamic programming algorithm can be more efficient.
Courcelle’s Theorem

If a graph property can be expressed in EMSO, then for every fixed \( w \geq 1 \), there is a linear-time algorithm for testing this property on graphs having treewidth at most \( w \).

**Note:** The constant depending on \( w \) can be very large (double, triple exponential etc.), therefore a direct dynamic programming algorithm can be more efficient.

If we can express a property in EMSO, then we immediately get that testing this property is FPT parameterized by the treewidth \( w \) of the input graph.

Can we express **3-Coloring** and **Hamiltonian Cycle** in EMSO?
Using Courcelle’s Theorem

<table>
<thead>

Using Courcelle’s Theorem

### 3-Coloring

\[ \exists C_1, C_2, C_3 \subseteq V \left( \forall v \in V \left( v \in C_1 \lor v \in C_2 \lor v \in C_3 \right) \right) \land \left( \forall u, v \in V \ adj(u, v) \rightarrow \left( \neg (u \in C_1 \land v \in C_1) \land \neg (u \in C_2 \land v \in C_2) \land \neg (u \in C_3 \land v \in C_3) \right) \right) \]

### Hamiltonian Cycle

\[ \exists H \subseteq E \left( \text{spanning}(H) \land \left( \forall v \in V \ \text{degree}2(H, v) \right) \right) \]

\[
\begin{align*}
\text{degree}0(H, v) &:= \neg \exists e \in H \ \text{inc}(e, v) \\
\text{degree}1(H, v) &:= \neg \text{degree}0(H, v) \land \left( \neg \exists e_1, e_2 \in H \ (e_1 \neq e_2 \land \text{inc}(e_1, v) \land \text{inc}(e_2, v)) \right) \\
\text{degree}2(H, v) &:= \neg \text{degree}0(H, v) \land \neg \text{degree}1(H, v) \land \left( \neg \exists e_1, e_2, e_3 \in H \ (e_1 \neq e_2 \land e_2 \neq e_3 \land e_1 \neq e_3 \land \text{inc}(e_1, v) \land \text{inc}(e_2, v) \land \text{inc}(e_3, v)) \right) \\
\text{spanning}(H) &:= \forall u, v \in V \ \exists P \subseteq H \ \forall x \in V \ \left( ((x = u \lor x = v) \land \text{degree}1(P, x)) \lor (x \neq u \land x \neq v \land (\text{degree}0(P, x) \lor \text{degree}2(P, x))) \right)
\end{align*}
\]
Using Courcelle’s Theorem

Two ways of using Courcelle’s Theorem:

1. The problem can be described by a single formula (e.g., **3-Coloring**, **Hamiltonian Cycle**).

   ⇒ Problem can be solved in time \( f(w) \cdot n \) for graphs of treewidth at most \( w \), i.e., FPT parameterized by treewidth.
Using Courcelle’s Theorem

Two ways of using Courcelle’s Theorem:

1. The problem can be described by a single formula (e.g., 3-Coloring, Hamiltonian Cycle).

   ⇒ Problem can be solved in time $f(w) \cdot n$ for graphs of treewidth at most $w$, i.e., FPT parameterized by treewidth.

2. The problem can be described by a formula for each value of the parameter $k$.

   Example: For each $k$, having a cycle of length exactly $k$ can be expressed as

   $$
   \exists v_1, \ldots, v_k \in V \left( (v_1 \neq v_2) \land (v_1 \neq v_3) \land \ldots (v_{k-1} \neq v_k) \right)
   \land (\text{adj}(v_1, v_2) \land \text{adj}(v_2, v_3) \land \ldots \land \text{adj}(v_{k-1}, v_k) \land \text{adj}(v_k, v_1)).
   $$

   ⇒ Problem can be solved in time $f(k, w) \cdot n$ for graphs of treewidth $w$, i.e., FPT parameterized with combined parameter $k$ and treewidth $w$. 
Subgraph Isomorphism

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.
### Subgraph Isomorphism

**Input:** graphs $H$ and $G$

**Find:** a copy of $H$ in $G$ as subgraph.

For each $H$, we can construct a formula $\phi_H$ that expresses “$G$ has a subgraph isomorphic to $H$” (similarly to the $k$-cycle on the previous slide).

$\Rightarrow$ By Courcelle’s Theorem, **Subgraph Isomorphism** can be solved in time $f(H, w) \cdot n$ if $G$ has treewidth at most $w$. 
**Subgraph Isomorphism**

**Input:** graphs $H$ and $G$

**Find:** a copy of $H$ in $G$ as subgraph.

Since there is only a finite number of simple graphs on $k$ vertices, **Subgraph Isomorphism** can be solved in time $f(k, w) \cdot n$ if $H$ has $k$ vertices and $G$ has treewidth at most $w$.

**Theorem**

**Subgraph Isomorphism** is FPT parameterized by combined parameter $k := |V(H)|$ and the treewidth $w$ of $G$. 
Theorem [Büchi, Elgot, Trakhtenbrot 1960]

If a language $L \subseteq \Sigma^*$ can be defined by an MSO formula $\phi$ using the relation $<$, then $L$ is regular.

Example: $a^*bc^*$ is defined by

$$\exists x : P_b(x) \land (\forall y : (y < x) \rightarrow P_a(y)) \land (\forall y : (x < y) \rightarrow P_c(y)).$$
MSO on words

**Theorem** [Büchi, Elgot, Trakhtenbrot 1960]

If a language $L \subseteq \Sigma^*$ can be defined by an MSO formula $\phi$ using the relation $<$, then $L$ is regular.

**Example:** $a^*bc^*$ is defined by

$$\exists x : P_b(x) \land (\forall y : (y < x) \rightarrow P_a(y)) \land (\forall y : (x < y) \rightarrow P_c(y)).$$

We prove a more general statement for formulas $\phi(w, X_1, \ldots, X_k)$ and words over $\Sigma \cup \{0, 1\}^k$, where $X_i$ is a subset of symbols of $w$.

Induction over the structure of $\phi$:

- FSM for $\neg \phi(w)$, given FSM for $\phi(w)$.
- FSM for $\phi_1(w) \land \phi_2(w)$, given FSMs for $\phi_1(w)$ and $\phi_2(w)$.
- FSM for $\exists X \phi(w, X)$, given FSM for $\phi(w, X)$.
- etc.
MSO on words

Theorem [Büchi, Elgot, Trakhtenbrot 1960]
If a language $L \subseteq \Sigma^*$ can be defined by an MSO formula $\phi$ using the relation $<$, then $L$ is regular.

Proving Courcelle’s Theorem:
- Generalize from words to trees.
- A width-$k$ tree decomposition can be interpreted as a tree over an alphabet of size $f(k)$.
- Formula $\Rightarrow$ tree automata.
Algorithms — overview

- Algorithms exploit the fact that a subtree communicates with the rest of the graph via a single bag.
- Key point: defining the subproblems.
- Courcelle’s Theorem makes this process automatic for many problems.
- There are notable problems that are easy for trees, but hard for bounded-treewidth graphs.
Treewidth — outline

1. Basic algorithms
2. Combinatorial properties
3. Applications
Properties of treewidth

**Fact:** Treewidth does not increase if we delete edges, delete vertices, or contract edges.

⇒ If $F$ is a minor of $G$, then the treewidth of $F$ is at most the treewidth of $G$. 
Properties of treewidth

**Fact:** Treewidth does not increase if we delete edges, delete vertices, or contract edges.

⇒ If $F$ is a **minor** of $G$, then the treewidth of $F$ is at most the treewidth of $G$.

**Fact:** For every clique $K$, there is a bag $B$ with $K \subseteq B$.

**Fact:** The treewidth of the $k$-clique is $k - 1$. 
Properties of treewidth

**Fact:** Treewidth does not increase if we delete edges, delete vertices, or contract edges.

⇒ If $F$ is a minor of $G$, then the treewidth of $F$ is at most the treewidth of $G$.

**Fact:** For every clique $K$, there is a bag $B$ with $K \subseteq B$.

**Fact:** The treewidth of the $k$-clique is $k - 1$.

**Fact:** For every $k \geq 2$, the treewidth of the $k \times k$ grid is exactly $k$.

\end{array}\]
The Cops and Robber game

**Game:** \( k \) cops try to capture a robber in the graph.
- In each step, the cops can move from vertex to vertex arbitrarily with helicopters.
- The robber moves infinitely fast on the edges, and sees where the cops will land.

**Theorem [Seymour and Thomas 1993]**

\( k+1 \) cops can win the game \( \iff \) the treewidth of the graph is at most \( k \).
The Cops and Robber game

**Game:** \(k\) cops try to capture a robber in the graph.
- In each step, the cops can move from vertex to vertex arbitrarily with helicopters.
- The robber moves infinitely fast on the edges, and sees where the cops will land.

**Theorem** [Seymour and Thomas 1993]

\[ k+1 \text{ cops can win the game } \iff \text{the treewidth of the graph is at most } k. \]

**Consequence 1: Algorithms**

The winner of the game can be determined in time \(n^{O(k)}\) using standard techniques (there are at most \(n^k\) positions for the cops)

\[ \Downarrow \]

For every fixed \(k\), it can be checked in polynomial-time if treewidth is at most \(k\).
The Cops and Robber game

**Game:** \( k \) cops try to capture a robber in the graph.

- In each step, the cops can move from vertex to vertex arbitrarily with helicopters.
- The robber moves infinitely fast on the edges, and sees where the cops will land.

**Theorem** [Seymour and Thomas 1993]

\[ k + 1 \] cops can win the game \( \iff \) the treewidth of the graph is at most \( k \).

**Consequence 2: Lower bounds**

**Exercise 1:**
Show that the treewidth of the \( k \times k \) grid is at least \( k - 1 \).
(E.g., robber can win against \( k - 1 \) cops.)

**Exercise 2:**
Show that the treewidth of the \( k \times k \) grid is at least \( k \).
(E.g., robber can win against \( k \) cops.)
The Cops and Robber game

Example: 2 cops have a winning strategy in a tree.

Theorem

The following are equivalent:

- $G$ does not have a $K_4$ minor.
- $G$ has treewidth $\leq 2$.
- $G$ is subgraph of a series-parallel graph.
A perfect structure theorem

Theorem
The following are equivalent:
- $G$ does not have a $K_4$ minor.
- $G$ has treewidth $\leq 2$.
- $G$ is subgraph of a series-parallel graph.

A perfect structure theorem:

\[ K_4 \not\in G \quad \iff \quad G \text{ has a width-2 tree decomposition} \]
\[ G \text{ has a width-2 tree decomposition} \quad \iff \quad K_4 \not\in G \]
Excluded Grid Theorem

Excluded Grid Theorem [Diestel et al. 1999]

If the treewidth of $G$ is at least $k^4k^2(k+2)$, then $G$ has a $k \times k$ grid minor.

(A $k^{O(1)}$ bound was just announced [Chekuri and Chuznoy 2013]!)
Excluded Grid Theorem

Excluded Grid Theorem [Diestel et al. 1999]

If the treewidth of $G$ is at least $k^4k^2(k+2)$, then $G$ has a $k \times k$ grid minor.

Observation: Every planar graph is the minor of a sufficiently large grid.

Consequence

If $H$ is planar, then every $H$-minor free graph has treewidth at most $f(H)$. 
Excluded Grid Theorem

Excluded Grid Theorem [Diestel et al. 1999]

If the treewidth of $G$ is at least $k^4k^2(k+2)$, then $G$ has a $k \times k$ grid minor.

A large grid minor is a “witness” that treewidth is large, but the relation is approximate:

- No $k \times k$ grid minor $\implies$ tree decomposition of width $< f(k)$
- Tree decomposition of width $< f(k)$ $\implies$ no $f(k) \times f(k)$ grid minor
Excluding trees

As every forest is planar, the following holds for every forest $F$:

- no $F$-minor $\implies$ tree decomposition of width $< f(F)$
- tree decomposition of width $< f(F)$ $\implies$ Does not exclude any tree as minor!

This is not a good (approximate) structure theorem.
Excluding trees

Path decomposition: the tree of bags is a path.
Pathwidth: defined analogously to treewidth.
Example: A complete binary tree on $k$ levels has pathwidth $k - 1$.

Theorem [Diestel 1995]
If $F$ is a forest, then every $F$-minor free graph has pathwidth at most $|V(F)| - 2$. 

```
Excluding trees
Path decomposition: the tree of bags is a path.
Pathwidth: defined analogously to treewidth.
Example: A complete binary tree on $k$ levels has pathwidth $k - 1$.

Theorem [Diestel 1995]
If $F$ is a forest, then every $F$-minor free graph has pathwidth at most $|V(F)| - 2$. 
```
Excluding trees

**Path decomposition**: the tree of bags is a path.

Pathwidth: defined analogously to treewidth.

**Example**: A complete binary tree on $k$ levels has pathwidth $k - 1$.

**Theorem** [Diestel 1995]

If $F$ is a forest, then every $F$-minor free graph has pathwidth at most $|V(F)| - 2$.

\[
\begin{align*}
\text{no } F\text{-minor} & \quad \Rightarrow \quad \text{path decomposition of width } < f(F) \\
\text{path decomposition of width } < f(F) & \quad \Rightarrow \quad \text{No } (f(F) + 1)\text{-level complete binary tree}
\end{align*}
\]
Planar Excluded Grid Theorem

For planar graphs, we get linear instead of exponential dependence:

**Theorem** [Robertson, Seymour, Thomas 1994]

Every **planar graph** with treewidth at least $5k$ has a $k \times k$ grid minor.
Outerplanar graphs

**Definition**
A planar graph is **outerplanar** if it has a planar embedding where every vertex is on the infinite face.

**Fact**
Every outerplanar graph has treewidth at most 2.

⇒ Every outerplanar graph is subgraph of a series-parallel graph.
**$k$-outerplanar graphs**

Given a planar embedding, we can define **layers** by iteratively removing the vertices on the infinite face.

**Definition**

A planar graph is **$k$-outerplanar** if it has a planar embedding having at most $k$ layers.

**Fact**

Every $k$-outerplanar graph has treewidth at most $3k + 1$. 
$k$-outerplanar graphs

Given a planar embedding, we can define layers by iteratively removing the vertices on the infinite face.

**Definition**

A planar graph is $k$-outerplanar if it has a planar embedding having at most $k$ layers.

**Fact**

Every $k$-outerplanar graph has treewidth at most $3k + 1$. 
**$k$-outerplanar graphs**

Given a planar embedding, we can define **layers** by iteratively removing the vertices on the infinite face.

**Definition**

   - The shifting technique
   - Bidimensionality
   - Complexity of CSP
Approximation schemes

**Definition**

A polynomial-time approximation scheme (PTAS) for a problem $P$ is an algorithm that takes an instance of $P$ and a rational number $\epsilon > 0$,

- always finds a $(1 + \epsilon)$-approximate solution,
- the running time is polynomial in $n$ for every fixed $\epsilon > 0$.

Typical running times: $2^{1/\epsilon} \cdot n$, $n^{1/\epsilon}$, $(n/\epsilon)^2$, $n^{1/\epsilon^2}$.

Some classical problems that have a PTAS:

- **Independent Set** for planar graphs
- **TSP** in the Euclidean plane
- **Steiner Tree** in planar graphs
- **Knapsack**
Baker’s shifting strategy for PTAS

Theorem

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for \textsc{Independent Set} for planar graphs.

Let $D := 1/\epsilon$. For a fixed $0 \leq s < D$, delete every layer $L_i$ with $i = s \pmod{D}$
Baker’s shifting strategy for PTAS

**Theorem**

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for **Independent Set** for planar graphs.

Let $D := 1/\epsilon$. For a fixed $0 \leq s < D$, delete every layer $L_i$ with $i = s \mod D$
Baker’s shifting strategy for PTAS

**Theorem**

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for **Independent Set** for planar graphs.

Let $D := 1/\epsilon$. For a fixed $0 \leq s < D$, delete every layer $L_i$ with $i = s \pmod{D}$
Baker’s shifting strategy for PTAS

**Theorem**

There is a \(2^{O\left(\frac{1}{\epsilon}\right)} \cdot n\) time PTAS for **Independent Set** for planar graphs.

Let \(D := \frac{1}{\epsilon}\). For a fixed \(0 \leq s < D\), delete every layer \(L_i\) with \(i = s \pmod{D}\).
Baker’s shifting strategy for PTAS

Theorem

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for Independent Set for planar graphs.

Let $D := 1/\epsilon$. For a fixed $0 \leq s < D$, delete every layer $L_i$ with $i = s \pmod{D}$
Baker’s shifting strategy for PTAS

**Theorem**

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for **Independent Set** for planar graphs.

- Let $D := 1/\epsilon$. For a fixed $0 \leq s < D$, delete every layer $L_i$ with $i = s \pmod{D}$.
- The resulting graph is $D$-outerplanar, hence it has treewidth at most $3D + 1 = O(1/\epsilon)$.
- Using the $2^{O(tw)} \cdot n$ time algorithm for **Independent Set**, the problem on the $D$-outerplanar graph can be solved in time $2^{O(1/\epsilon)} \cdot n$. 

Theorem

There is a $2^{O(1/\epsilon)} \cdot n$ time PTAS for **Independent Set** for planar graphs.

We do this for every $0 \leq s < D$:
- for at least one value of $s$, we delete at most $1/D = \epsilon$ fraction of the solution

\[ \downarrow \]

We get a $(1 + \epsilon)$-approximate solution.
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$

Find: a copy of $H$ in $G$ as subgraph.
Baker’s shifting strategy for FPT

**SUBGRAPH ISOMORPHISM**

Input: graphs \( H \) and \( G \)
Find: a copy of \( H \) in \( G \) as subgraph.

- For a fixed \( 0 \leq s < k + 1 \), delete every layer \( L_i \) with \( i = s \) \((\text{mod } k + 1)\)
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.

For a fixed $0 \leq s < k + 1$, delete every layer $L_i$ with $i = s$ (mod $k + 1$)
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.

For a fixed $0 \leq s < k + 1$, delete every layer $L_i$ with $i = s \pmod {k + 1}$
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

**Input:** graphs $H$ and $G$

**Find:** a copy of $H$ in $G$ as subgraph.

- For a fixed $0 \leq s < k + 1$, delete every layer $L_i$ with $i = s \pmod{k + 1}$
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.

- For a fixed $0 \leq s < k + 1$, delete every layer $L_i$ with $i = s \pmod{k + 1}$
- The resulting graph is $k$-outerplanar, hence it has treewidth at most $3k + 1$.
- Using the $f(k, tw) \cdot n$ time algorithm for Subgraph Isomorphism, the problem can be solved in time $f(k, 3k + 1) \cdot n$. 
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$  
Find: a copy of $H$ in $G$ as subgraph.

We do this for every $0 \leq s < k + 1$:  
for at least one value of $s$, we do not delete any of the $k$ vertices of the solution  

$\Downarrow$

We find a copy of $H$ in $G$ if there is one.
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.

We do this for every $0 \leq s < k + 1$: for at least one value of $s$, we do not delete any of the $k$ vertices of the solution

⇓

We find a copy of $H$ in $G$ if there is one.
Baker’s shifting strategy for FPT

\textbf{Subgraph Isomorphism}

Input: graphs $H$ and $G$
Find: a copy of $H$ in $G$ as subgraph.

We do this for every $0 \leq s < k + 1$:
for at least one value of $s$, we do not delete
any of the $k$ vertices of the solution

\[\Downarrow\]

We find a copy of $H$ in $G$ if there is one.
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

Input: graphs \( H \) and \( G \)
Find: a copy of \( H \) in \( G \) as subgraph.

We do this for every \( 0 \leq s < k + 1 \):
for at least one value of \( s \), we do not delete
any of the \( k \) vertices of the solution

\( \downarrow \)

We find a copy of \( H \) in \( G \) if there is one.
Baker’s shifting strategy for FPT

**Subgraph Isomorphism**

**Input:** graphs $H$ and $G$

**Find:** a copy of $H$ in $G$ as subgraph.

**Theorem**

*Subgraph Isomorphism* for planar graphs is FPT parameterized by $k := |V(H)|$. 

Baker’s shifting strategy for FPT

- The technique is very general, works for many problems on planar graphs:
  - **Independent Set**
  - **Vertex Cover**
  - **Dominating Set**
  - ...

- More generally: First-Order Logic problems.

- But for some of these problems, much better techniques are known (see the following slides).
Bidimensionality

A powerful framework for efficient algorithms on planar graphs.

Setup:

- Let $x(G)$ be some graph invariant (i.e., an integer associated with each graph).
- Given $G$ and $k$, we want to decide if $x(G) \leq k$ (or $x(G) \geq k$).
- Typical examples:
  - Maximum independent set size.
  - Minimum vertex cover size.
  - Length of the longest path.
  - Minimum dominating set size.
  - Minimum feedback vertex set size.

Bidimensionality [Demaine, Fomin, Hajiaghayi, Thilikos 2005]

For many natural invariants, we can do this in time $2^{O(\sqrt{k})} \cdot n^{O(1)}$ on planar graphs.
Bidimensionality for \textsc{Vertex Cover}

**Observation:** If the treewidth of a planar graph $G$ is at least $5\sqrt{2k}$

$\Rightarrow$ It has a $\sqrt{2k} \times \sqrt{2k}$ grid minor (Planar Excluded Grid Theorem)

$\Rightarrow$ The grid has a matching of size $k$

$\Rightarrow$ Vertex cover size is at least $k$ in the grid.

$\Rightarrow$ Vertex cover size is at least $k$ in $G$. 

We use this observation to solve \textsc{Vertex Cover} on planar graphs:
Bidimensionality for **Vertex Cover**

**Observation:** If the treewidth of a planar graph $G$ is at least $5\sqrt{2k}$
⇒ It has a $\sqrt{2k} \times \sqrt{2k}$ grid minor (Planar Excluded Grid Theorem)
⇒ The grid has a matching of size $k$
⇒ Vertex cover size is at least $k$ in the grid.
⇒ Vertex cover size is at least $k$ in $G$.

We use this observation to solve **Vertex Cover** on planar graphs:

- Set $w := 5\sqrt{2k}$.
- Find a 4-approximate tree decomposition.
  - If treewidth is at least $w$: we answer “vertex cover is $\geq k$.”
  - If we get a tree decomposition of width $4w$, then we can solve the problem in time $2^{O(w)} \cdot n^{O(1)} = 2^{O(\sqrt{k})} \cdot n^{O(1)}$. 
Bidimensionality

Definition

A graph invariant $x(G)$ is **minor-bidimensional** if

- $x(G') \leq x(G)$ for every minor $G'$ of $G$, and
- If $G_k$ is the $k \times k$ grid, then $x(G_k) \geq ck^2$

(for some constant $c > 0$).

Examples: minimum vertex cover, length of the longest path, feedback vertex set are minor-bidimensional.
Bidimensionality

Definition

A graph invariant $x(G)$ is minor-bidimensional if

1. $x(G') \leq x(G)$ for every minor $G'$ of $G$, and
2. If $G_k$ is the $k \times k$ grid, then $x(G_k) \geq ck^2$ (for some constant $c > 0$).

Examples: minimum vertex cover, length of the longest path, feedback vertex set are minor-bidimensional.
Bidimensionality

Definition

A graph invariant $x(G)$ is **minor-bidimensional** if

- $x(G') \leq x(G)$ for every minor $G'$ of $G$, and
- If $G_k$ is the $k \times k$ grid, then $x(G_k) \geq ck^2$
  (for some constant $c > 0$).

Examples: minimum vertex cover, length of the longest path, feedback vertex set are minor-bidimensional.
Bidimensionality (cont.)

We can answer “$x(G) \geq k$?” for a minor-bidimensional invariant the following way:

- Set $w := c \sqrt{k}$ for an appropriate constant $c$.
- Use the 4-approximation tree decomposition algorithm.
  - If treewidth is at least $w$: $x(G)$ is at least $k$.
  - If we get a tree decomposition of width $4w$, then we can solve the problem using dynamic programming on the tree decomposition.

Running time:

- If we can solve the problem on tree decomposition of width $w$ in time $2^{O(w)} \cdot n^{O(1)}$, then the running time is $2^{O(\sqrt{k})} \cdot n^{O(1)}$.
- If we can solve the problem on tree decomposition of width $w$ in time $w^{O(w)} \cdot n^{O(1)}$, then the running time is $2^{O(\sqrt{k} \log k)} \cdot n^{O(1)}$. 

Definition

A graph invariant $x(G)$ is minor-bidimensional if

- $x(G') \leq x(G)$ for every minor $G'$ of $G$, and
- If $G_k$ is the $k \times k$ grid, then $x(G_k) \geq ck^2$
  (for some constant $c > 0$).

**Exercise:** Dominating Set is not minor-bidimensional.
Contraction bidimensionality

**Definition**

A graph invariant $x(G)$ is **minor-bidimensional** if

- $x(G') \leq x(G)$ for every minor $G'$ of $G$, and
- If $G_k$ is the $k \times k$ grid, then $x(G_k) \geq ck^2$
  (for some constant $c > 0$).

**Exercise:** **Dominating Set** is **not** minor-bidimensional.

We fix the problem by allowing only contractions but not edge/vertex deletions.
Theorem

Every planar graph with treewidth at least $5k$ can be contracted to a partially triangulated $k \times k$ grid.
Contraction bidimensionality

**Definition**

A graph invariant \( x(G) \) is **contraction-bidimensional** if

- \( x(G') \leq x(G) \) for every contraction \( G' \) of \( G \), and
- If \( G_k \) is a \( k \times k \) partially triangulated grid, then \( x(G_k) \geq ck^2 \) (for some constant \( c > 0 \)).
Contraction bidimensionality

**Definition**

A graph invariant $x(G)$ is **contraction-bidimensional** if

- $x(G') \leq x(G)$ for every contraction $G'$ of $G$, and
- If $G_k$ is a $k \times k$ partially triangulated grid, then $x(G_k) \geq ck^2$ (for some constant $c > 0$).

**Example:** minimum dominating set, maximum independent set are contraction-bidimensional.
Contraction bidimensionality

Definition

A graph invariant $x(G)$ is **contraction-bidimensional** if

- $x(G') \leq x(G)$ for every contraction $G'$ of $G$, and
- If $G_k$ is a $k \times k$ partially triangulated grid, then $x(G_k) \geq ck^2$ (for some constant $c > 0$).

Example: minimum dominating set, **maximum independent set** are contraction-bidimensional.
Bidimensionality for Dominating Set

The size of a minimum dominating set is a contraction bidimensional invariant: we need at least \((k - 2)^2 / 9\) vertices to dominate all the internal vertices of a partially triangulated \(k \times k\) grid (since a vertex can dominate at most 9 internal vertices).

**Theorem**

Given a tree decomposition of width \(w\), Dominating Set can be solved in time \(3^w \cdot w^{O(1)} \cdot n^{O(1)}\).

Solving Dominating Set on planar graphs:

- Set \(w := 5(3\sqrt{k} + 2)\).
- Use the 4-approximation tree decomposition algorithm.
  - If treewidth is at least \(w\): we answer 'dominating set is \(\geq k\)'.
  - If we get a tree decomposition of width \(4w\), then we can solve the problem in time \(3^w \cdot n^{O(1)} = 2^{O(\sqrt{k})} \cdot n^{O(1)}\).
Constraint Satisfaction Problems (CSP)

A CSP instance is given by describing the
- variables,
- domain of the variables,
- constraints on the variables.

**Task:** Find an assignment that satisfies every constraint.

\[ I = C_1(x_1, x_2, x_3) \land C_2(x_2, x_4) \land C_3(x_1, x_3, x_4) \]
Constraint Satisfaction Problems (CSP)

A CSP instance is given by describing the
- variables,
- domain of the variables,
- constraints on the variables.

**Task:** Find an assignment that satisfies every constraint.

\[ I = C_1(x_1, x_2, x_3) \land C_2(x_2, x_4) \land C_3(x_1, x_3, x_4) \]

**Examples:**
- **3SAT:** 2-element domain, every constraint is ternary
- **Vertex Coloring:** domain is the set of colors, binary constraints
- **k-Clique** (in graph \( G \)): \( k \) variables, domain is the vertices of \( G \), \( \binom{k}{2} \) binary constraints
Graphs and hypergraphs related to CSP

**Gaifman/primal graph:** vertices are the variables, two variables are adjacent if they appear in a common constraint.

**Incidence graph:** bipartite graph, vertices are the variables and constraints.

**Hypergraph:** vertices are the variables, constraints are the hyperedges.

\[ I = C_1(x_2, x_1, x_3) \land C_2(x_4, x_3) \land C_3(x_1, x_4, x_2) \]
**Theorem [Freuder 1990]**

For every fixed $k$, CSP can be solved in polynomial time if the primal graph of the instance has treewidth at most $k$.

**Proof sketch:**

- Find a tree decomposition of width $k$ (linear-time for fixed $k$).
- For each bag, enumerate every assignment of the bag that satisfies every constraint fully contained in the bag. Each bag has at most $k + 1$ variables, thus there are at most $|D|^{k+1}$ such assignments for each bag.
- Use bottom-up DP to find a satisfying assignment.
- Each constraint induces a clique in the primal graph, thus each constraint is fully contained in one of the bags.
- Running time of DP is polynomial in $|D|^{k+1}$ and the number of variables.
Dichotomy for binary CSP

**Binary CSP:** Every constraint is of arity 2.

We know that binary \( \text{CSP}(G) \) is polynomial-time solvable for every class \( G \) of graphs with bounded treewidth. Are there other polynomial cases?
Dichotomy for binary CSP

**Binary CSP:** Every constraint is of arity 2.

We know that binary \( \text{CSP}(G) \) is polynomial-time solvable for every class \( G \) of graphs with bounded treewidth. Are there other polynomial cases?

---

**Theorem [Grohe-Schwentick-Segoufin 2001]**

Let \( G \) be a recursively enumerable class of graphs. Assuming \( \text{FPT} \neq W[1] \), the following are equivalent:

- Binary \( \text{CSP}(G) \) is polynomial-time solvable.
- Binary \( \text{CSP}(G) \) is FPT.
- \( G \) has bounded treewidth.
Dichotomy for binary CSP

**Binary CSP:** Every constraint is of arity 2.

We know that binary CSP\((G)\) is polynomial-time solvable for every class \(G\) of graphs with bounded treewidth. Are there other polynomial cases?

---

**Theorem** [Grohe-Schwentick-Segoufin 2001]

Let \(G\) be a recursively enumerable class of graphs. Assuming FPT \(\neq W[1]\), the following are equivalent:

- Binary CSP\((G)\) is polynomial-time solvable.
- Binary CSP\((G)\) is FPT.
- \(G\) has bounded treewidth.

**Note:** FPT \(\neq W[1]\) is a standard complexity assumption.

**Note:** Fixed-parameter tractability does not give us more power here than polynomial-time solvability.
Proof outline

Suppose that $G$ has unbounded treewidth, but $\text{CSP}(G)$ is FPT.

- Assuming $\text{FPT} \neq \text{W}[1]$, there is no $f(k)n^c$ time algorithm for $k$-CLIQUE. But we can solve $k$-CLIQUE the following way:
  - Formulate $k$-CLIQUE as a binary CSP instance on the $k \times k$ grid.
  - Find a $G_k \in G$ containing a $k \times k$ minor (there is such a $G_k$ by the Excluded Grid Theorem).
  - Reduce CSP on the $k \times k$ grid to CSP with graph $G_k$, which is an instance of $\text{CSP}(G)$.
  - Use the assumed algorithm for $\text{CSP}(G)$.
  - The running time is $f(k)n^c$: the nonpolynomial factors in the running time depend only on $k$ (finding $G_k$, size of $G_k$, solving $\text{CSP}(G)$).

$\Rightarrow k$-CLIQUE is FPT, contradicting the hypothesis $\text{FPT} \neq \text{W}[1]$. 
Treewidth — overview

- **Algorithms**
  - Dynamic programming
  - Courcelle’s Theorem

- **Properties**
  - Characterization by the Cops and Robber game.
  - Excluding a grid, excluding a tree.
  - $k$-outerplanar graphs.

- **Applications**
  - Shifting technique for PTAS and FPT.
  - Minor/contraction bidimensionality.
  - Excluded Grid Theorem in the classification of $\text{CSP}(\mathcal{G})$. 
Treewidth

**Tree decomposition:** Vertices are arranged in a tree structure satisfying the following properties:

1. If \( u \) and \( v \) are neighbors, then there is a bag containing both of them.
2. For every \( v \), the bags containing \( v \) form a connected subtree.

**Width of the decomposition:** largest bag size \(-1\).

**treewidth:** width of the best decomposition.
Surfaces
A topological surface is a nonempty second countable Hausdorff topological space in which every point has an open neighborhood homeomorphic to some open subset of the Euclidean plane $E^2$.

Intuitively: something thin floating in space.

Our viewpoint: which graphs can be drawn on the different surfaces, thus we do not distinguish surfaces that are homeomorphic.
Planar graphs

The following are equivalent:

- Graph $G$ can be drawn on the plane.
- Graph $G$ can be drawn inside a disc.
- Graph $G$ can be drawn on the sphere.
Euler’s Formula

**Theorem**

If $G$ is a connected simple graph drawn in the plane with $v$ vertices, $e$ edges, and $f$ faces, then

$$v + f = e + 2.$$ 

**Example:**

$v = 8$
$f = 6$
$e = 12$
Euler’s Formula

**Theorem**

If $G$ is a connected simple graph drawn in the plane with $v$ vertices, $e$ edges, and $f$ faces, then

$$v + f = e + 2.$$

**Example:**

$v = 8$

$f = 6$

$e = 12$

**Consequence:** $e \leq 3v - 6$

**Proof:** $2e \geq 3f$ (every face has at least 3 edges)

$e = v + f - 2 \leq v + \frac{2}{3}e - 2$

$\frac{1}{3}e \leq v - 2$

$e \leq 3v - 6$
Examples of surfaces: disk

Rectangle with boundary: same as disk.
Examples of surfaces: cylinder

Gluing together the vertical sides creates a cylinder.
Examples of surfaces: torus

Gluing together both the two horizontal and the two vertical sides creates a torus.
Examples of surfaces: torus

Gluing together both the two horizontal and the two vertical sides creates a torus.

$K_5$ can be drawn on the torus.

Exercise: draw $K_7$ on the torus.
Examples of surfaces: sphere

Gluing together top with left and bottom with right creates a sphere.
Examples of surfaces: Möbius strip

Gluing together the vertical sides in twisted way creates a Möbius strip.
Examples of surfaces: real projective plane

Gluing together both the horizontal and vertical sides in a twisted way creates a real projective plane, which is a sphere with a cross cap.
Examples of surfaces: Klein bottle

Gluing together both the horizontal sides in a normal and the vertical sides in a twisted way creates a Klein bottle, which is a sphere with two cross caps.
Examples of surfaces: Klein bottle

Gluing together both the horizontal sides in a normal and the vertical sides in a twisted way creates a Klein bottle, which is a sphere with two cross caps.
Examples of surfaces: Klein bottle

Gluing together both the horizontal sides in a normal and the vertical sides in a twisted way creates a Klein bottle, which is a sphere with two cross caps.
Orientable vs. nonorientable

Definition

A surface $\Sigma$ is **orientable** if whenever a graph is drawn on $\Sigma$ such that every face is a disk, then each face can be assigned an orientation such that two faces sharing an edge give the opposite orientation to that edge.

- The sphere and the torus are orientable.
- The Möbius strip and the Klein bottle are nonorientable.
Surfaces with boundaries

Some surfaces have boundaries:

- The cylinder and the Möbius strip have boundaries.
- The sphere, torus, Klein bottle are closed surfaces.
Some surfaces have boundaries:

- The cylinder and the Möbius strip have boundaries.
- The sphere, torus, Klein bottle are **closed surfaces**.

Every surface with boundaries can be obtained from a closed surface by removing some number of disks.

As removing disks does not change which graphs can be embedded, we consider only closed surfaces from now.
Classification of closed surfaces

Theorem [Brahana 1921]

Every closed surface is equivalent either to

- a sphere with $k \geq 0$ handles (orientable surfaces), or
- or to a sphere with $k \geq 1$ crosscaps (nonorientable surfaces).
Classification of closed surfaces

Theorem [Brahana 1921]

Every closed surface is equivalent either to
- a sphere with \( k \geq 0 \) handles (orientable surfaces), or
- or to a sphere with \( k \geq 1 \) crosscaps (nonorientable surfaces).

Alternative version:

Theorem [Brahana 1921]

Every closed surface is equivalent to a sphere with \( k \geq 0 \) handles and 0, 1, or 2 crosscaps attached to it.
5 handles, 2 crosscaps
Euler’s formula

**Theorem**

Let $G$ be a connected simple graph drawn on a closed surface $\Sigma$ such that every face is a disk. If $G$ has $v$ vertices, $e$ edges, and $f$ faces, then

$$v + f = e + 2 - \text{eg}(\Sigma),$$

where the **Euler genus** $\text{eg}(\Sigma)$ is

- $2k$ if $\Sigma$ is a sphere with $k$ handles, and
- $k$ if $\Sigma$ is a sphere with $k$ crosscaps.

**Consequence:** $e \leq 3v - 6 + 3\text{eg}(\Sigma)$

Bounded-genus graphs have bounded average degree.
Can we generalize the powerful techniques from planar graphs to surfaces?

- **Shifting strategy** for approximation schemes/parameterized algorithms

  **Crucial tool:** bounding the treewidth of $k$-outerplanar graphs.

- **Subexponential algorithms** for minor/contraction-bidimensional problems.

  **Crucial tool:** grid theorems.
Grid theorems

**Theorem**
Every **planar graph** with treewidth at least $5k$ has a $k \times k$ grid minor.

**Theorem** [Demaine, Fomin, Hajiaghayi, Thilikos 2005]
If $G$ is a graph drawn on $\Sigma$ and has treewidth at least $c(\text{eg}(\Sigma) + 1) \cdot k$, then $G$ has a $k \times k$ grid minor.
Grid theorems

**Theorem**

Every **planar graph** with treewidth at least $5k$ has a $k \times k$ grid minor.

**Theorem** [Demaine, Fomin, Hajiaghayi, Thilikos 2005]

If $G$ is a graph drawn on $\Sigma$ and has treewidth at least $c(\text{eg}(\Sigma) + 1) \cdot k$, then $G$ has a $k \times k$ grid minor.

Subexponential parameterized algorithms for e.g., $k$-**VERTEX COVER** go through:

- either the graph has a $\Omega(\sqrt{k}) \times \Omega(\sqrt{k})$ grid minor and then the vertex cover size is at least $k$, or
- treewidth is $O(\sqrt{k}(\text{eg}(\Sigma) + 1))$ and we can solve the problem in time $2^{O(\sqrt{k}(\text{eg}(\Sigma)+1))} \cdot n^{O(1)}$. 

Grid theorems

**Theorem**
Every **planar graph** with treewidth at least $5k$ has a $k \times k$ grid minor.

**Theorem** [Demaine, Fomin, Hajiaghayi, Thilikos 2005]
If $G$ is a graph drawn on $\Sigma$ and has treewidth at least $c(\text{eg}(\Sigma) + 1) \cdot k$, then $G$ has a $k \times k$ grid minor.

Subexponential parameterized algorithms for e.g., $k$-**Vertex Cover** go through:

- either the graph has a $\Omega(\sqrt{k}) \times \Omega(\sqrt{k})$ grid minor and then the vertex cover size is at least $k$, or
- treewidth is $O(\sqrt{k}(\text{eg}(\Sigma) + 1))$ and we can solve the problem in time $2^{O(\sqrt{k}(\text{eg}(\Sigma)+1))} \cdot n^{O(1)}$.

Similar (more complicated) generalizations for contraction-bidimensional problems.
The shifting technique relied on the fact that the treewidth of $k$-outerplanar graphs have bounded treewidth.

**Definition**

A class $G$ of graphs has **bounded local treewidth** if there is a function $f$ such that $\text{tw}(G) \leq f(\text{diam}(G))$ for every $G \in G$.

Bounded genus implies bounded local treewidth:

**Theorem**

The class $G_\Sigma$ of graphs embeddable into $\Sigma$ has bounded local treewidth with $\text{tw}(G) \leq 3\text{eg}(\Sigma)\text{diam}(G)$.
Local treewidth

\( B_v[d] \): the ball containing vertices at distance \( \leq d \) from \( v \).
\( R_v[x, y] \) the ring containing vertices at distance \( x \leq d \leq y \) from \( v \).

Lemma

Let \( \mathcal{G} \) be a **minor-closed** class of graphs having **bounded local treewidth**. Then the treewidth of \( R_v[x, y] \) can be bounded by a function of \( y - x + 1 \).
Local treewidth

$B_v[d]$ : the ball containing vertices at distance $\leq d$ from $v$.
$R_v[x, y]$ the ring containing vertices at distance $x \leq d \leq y$ from $v$.

Lemma

Let $\mathcal{G}$ be a minor-closed class of graphs having bounded local treewidth. Then the treewidth of $R_v[x, y]$ can be bounded by a function of $y - x + 1$.

Proof:

- Contract $B_v[x - 1]$.
- Ring $R_v[x, y]$ appears now at distance $y - x + 1$ from $v$.
- The ring appears in a graph of treewidth $f(y - x + 1)$. 
Local treewidth

$B_v[d]$ : the ball containing vertices at distance $\leq d$ from $v$.  
$R_v[x, y]$ the ring containing vertices at distance $x \leq d \leq y$ from $v$.

Lemma

Let $G$ be a minor-closed class of graphs having bounded local treewidth. Then the treewidth of $R_v[x, y]$ can be bounded by a function of $y - x + 1$.

Proof:

- Contract $B_v[x - 1]$.
- Ring $R_v[x, y]$ appears now at distance $y - x + 1$ from $v$.
- The ring appears in a graph of treewidth $f(y - x + 1)$.
Theorem

If $G$ is minor-closed and has bounded local treewidth, then **Independent Set** has a PTAS on $G$.

- Repeat the following for $i = 0, \ldots, D$, where $D = \lceil 1/\epsilon \rceil$.
- Pick a vertex $v$ and remove every vertex at distance $jD + i$ for $j = 0, 1, \ldots$.
- The graph falls apart into disjoint rings $R_v[0, i - 1]$, $R_v[i + 1, D + i - 1]$, $R_v[D + i + 1, 2D + i - 1]$, $\ldots$.
- Thus treewidth is $f(D)$, i.e., can be bounded as function of $\epsilon$.
- Problem can be solved in time $f(1/\epsilon) \cdot n$.
- At least one choice of $i$ removes at most an $\epsilon$ fraction of the optimum solution.
A potential source of confusion

- 3-regular graphs have bounded local treewidth: if diameter is $d$, then there are at most $\sum_{i=0}^{d} 3^i = (3^{d+1} - 1)/2$ vertices, hence treewidth is bounded by a function of $d$.

- **Independent Set** is APX-hard on 3-regular graphs, thus it has no PTAS unless $P = NP$.

Have we just proved $P = NP$?
Bounded degree

A potential source of confusion

- 3-regular graphs have bounded local treewidth: if diameter is $d$, then there are at most $\sum_{i=0}^{d} 3^i = (3^{d+1} - 1)/2$ vertices, hence treewidth is bounded by a function of $d$.

- **Independent Set** is APX-hard on 3-regular graphs, thus it has no PTAS unless $P = \text{NP}$.

Have we just proved $P = \text{NP}$?

**Theorem**

If $G$ is a **minor-closed** and has bounded local treewidth, then **Independent Set** has a PTAS on $G$.

Local treewidth is useful only for **minor-closed** classes!
Local treewidth

**Theorem [Frick and Grohe 2001]**

If a graph property can be expressed in first-order logic and $\mathcal{G}$ is a class of graphs with bounded local treewidth, then there is a linear-time algorithm for testing this property on members of $\mathcal{G}$.

**Note:** we do not need here that $\mathcal{G}$ is closed under taking minors.

Shows, e.g., that **Subgraph Isomorphism** is FPT on planar graphs or on bounded-degree graphs.

**Exercise:** Can this result be generalized to EMSO instead of first-order logic?
Excluding minors
Definition

Graph $H$ is a minor $G$ ($H \leq G$) if $H$ can be obtained from $G$ by deleting edges, deleting vertices, and contracting edges.
Minors

Equivalent definition

Graph $H$ is a minor of $G$ if there is a mapping $\phi$ (the minor model) that maps each vertex of $H$ to a connected subset of $G$ such that

- $\phi(u)$ and $\phi(v)$ are disjoint if $u \neq v$, and
- if $uv \in E(G)$, then there is an edge between $\phi(u)$ and $\phi(v)$. 
Equivalent definition

Graph $H$ is a **minor** of $G$ if there is a mapping $\phi$ (the minor model) that maps each vertex of $H$ to a connected subset of $G$ such that

- $\phi(u)$ and $\phi(v)$ are disjoint if $u \neq v$, and
- if $uv \in E(G)$, then there is an edge between $\phi(u)$ and $\phi(v)$.

![Graph H as a minor of G](image)
Excluding minors

Connection to surfaces:

- Graphs excluding $K_5$- and $K_{3,3}$-minors are planar.
- Graphs that can be drawn on a fixed surface (e.g., torus) can be characterized by a finite list of excluded minors.

Is it true for every $H$ that $H$-minor free graphs can be drawn on a fixed surface?
Excluding minors

Connection to surfaces:

- Graphs that can be drawn on a fixed surface (e.g., torus) can be characterized by a finite list of excluded minors.

Is it true for every $H$ that $H$-minor free graphs can be drawn on a fixed surface?

**NO** (clique sums), **NO** (apices), **NO** (vortices)
Excluding minors

Connection to surfaces:

- Graphs excluding $K_5$- and $K_{3,3}$-minors are planar.
- Graphs that can be drawn on a fixed surface (e.g., torus) can be characterized by a finite list of excluded minors.

Is it true for every $H$ that $H$-minor free graphs can be drawn on a fixed surface?

**NO** (clique sums), **NO** (apices), **NO** (vortices)

**YES** (in a sense — Robertson-Seymour Structure Theorem)
Excluding minors

The following graph does not have a $K_6$-minor, but its genus can be large:

Connecting bounded-genus graphs can increase genus without creating a clique minor.
Clique sums

Definition

Let $G_1$ and $G_2$ be two graphs with two cliques $K_1 \subseteq V(G_1)$ and $K_2 \subseteq V(G_2)$ of the same size. Graph $G$ is a **clique sum** of $G_1$ and $G_2$ if it can be obtained by identifying $K_1$ and $K_2$, and then removing some of the edges of the clique.
Clique sums

**Definition**
Let $G_1$ and $G_2$ be two graphs with two cliques $K_1 \subseteq V(G_1)$ and $K_2 \subseteq V(G_2)$ of the same size. Graph $G$ is a **clique sum** of $G_1$ and $G_2$ if it can be obtained by identifying $K_1$ and $K_2$, and then removing some of the edges of the clique.
Clique sums

Definition

Let $G_1$ and $G_2$ be two graphs with two cliques $K_1 \subseteq V(G_1)$ and $K_2 \subseteq V(G_2)$ of the same size. Graph $G$ is a **clique sum** of $G_1$ and $G_2$ if it can be obtained by identifying $K_1$ and $K_2$, and then removing some of the edges of the clique.
Clique sums

Observation

If $K_k \not\subseteq G_1, G_2$ and $G$ is a clique sum of $G_1$ and $G_2$, then $K_k \not\subseteq G$.

Thus we can build $K_k$-minor-free graphs by repeated clique sums.
Clique sums

**Observation**

If $K_k \not\leq G_1, G_2$ and $G$ is a clique sum of $G_1$ and $G_2$, then $K_k \not\leq G$.

Thus we can build $K_k$-minor-free graphs by repeated clique sums.

**Proof:**

For either $i = 1$ or $i = 2$, every set in the model of $K_k$ in $G$ intersects $V(G_i)$. Restricting to $V(G_i)$ gives a model of $K_k$ in $G_i$ (using that the separator is a clique).
Clique sums

**Observation**

If $K_k \not\subseteq G_1, G_2$ and $G$ is a clique sum of $G_1$ and $G_2$, then $K_k \not\subseteq G$.

Thus we can build $K_k$-minor-free graphs by repeated clique sums.

**Proof:**

For either $i = 1$ or $i = 2$, every set in the model of $K_k$ in $G$ intersects $V(G_i)$. Restricting to $V(G_i)$ gives a model of $K_k$ in $G_i$ (using that the separator is a clique).
Excluding $K_5$

**Theorem [Wagner 1937]**

A graph is $K_5$-minor-free if and only if it can be built from planar graphs and $V_8$ by repeated clique sums.
Tree decomposition: Vertices are arranged in a tree structure satisfying the following properties:

1. If $u$ and $v$ are neighbors, then there is a bag containing both of them.
2. For every $v$, the bags containing $v$ form a connected subtree.
Torso of a bag: we make the intersections with the adjacent bags cliques.
Torso

Torso of a bag: we make the intersections with the adjacent bags cliques.
Torso of a bag: we make the intersections with the adjacent bags cliques.
Torso of a bag: we make the intersections with the adjacent bags cliques.
Torso

**Torso of a bag**: we make the intersections with the adjacent bags cliques.
Torso

**Torso of a bag:** we make the intersections with the adjacent bags cliques.
Torso

Torso of a bag: we make the intersections with the adjacent bags cliques.
Excluding $K_5$ — restated

**Theorem [Wagner 1937]**

A graph is $K_5$-minor-free if and only if it can be built from planar graphs and $V_8$ by repeated clique sums.

Equivalently:

**Theorem [Wagner 1937]**

A graph is $K_5$-minor-free if and only if it has a tree decomposition where every torso is either a planar graph or the graph $V_8$. 
Apex vertices

The graph formed from a grid by attaching a universal vertex is $K_6$-minor-free, but has large genus.

- A planar graph + $k$ extra vertices has no $K_{k+5}$-minor.
- Instead of bounded genus graphs, our building blocks should be “bounded genus graphs + a bounded number of apex vertices connected arbitrarily.”
Vortices

One can show that the following graph has large genus, but cannot have a $K_8$-minor.

Removing a few apex vertices or decomposing by clique sums do not help.
Vortices

- A **vortex** of width $k$ and perimeter $v_1, \ldots, v_n$ is a graph $F$ that has a width-$k$ path decomposition $B_1, \ldots, B_n$ such that $v_i \in B_i$.

- Let $G$ be embedded in $\Sigma$ and let $D$ be a disk intersecting $G$ only in vertices $v_1, \ldots, v_n$. Attaching a vortex on $D$ means taking the union of $G$ and a vortex on $v_1, \ldots, v_n$ (the vortex intersects $G$ only in these vertices).

![Diagram of a vortex with vertices $v_1, v_2, v_3, v_4, v_5, v_6, v_7$. The vortex consists of two separate loops connected by edges.](image-url)
Vortices

- A **vortex** of width $k$ and perimeter $v_1, \ldots, v_n$ is a graph $F$ that has a width-$k$ path decomposition $B_1, \ldots, B_n$ such that $v_i \in B_i$.
- Let $G$ be embedded in $\Sigma$ and let $D$ be a disk intersecting $G$ only in vertices $v_1, \ldots, v_n$. Attaching a vortex on $D$ means taking the union of $G$ and a vortex on $v_1, \ldots, v_n$ (the vortex intersects $G$ only in these vertices).
Vortices

- A vortex of width $k$ and perimeter $v_1, \ldots, v_n$ is a graph $F$ that has a width-$k$ path decomposition $B_1, \ldots, B_n$ such that $v_i \in B_i$.
- Let $G$ be embedded in $\Sigma$ and let $D$ be a disk intersecting $G$ only in vertices $v_1, \ldots, v_n$. Attaching a vortex on $D$ means taking the union of $G$ and a vortex on $v_1, \ldots, v_n$ (the vortex intersects $G$ only in these vertices).
**Vortices**

- A vortex of width $k$ and perimeter $v_1, \ldots, v_n$ is a graph $F$ that has a width-$k$ path decomposition $B_1, \ldots, B_n$ such that $v_i \in B_i$.
- Let $G$ be embedded in $\Sigma$ and let $D$ be a disk intersecting $G$ only in vertices $v_1, \ldots, v_n$. Attaching a vortex on $D$ means taking the union of $G$ and a vortex on $v_1, \ldots, v_n$ (the vortex intersects $G$ only in these vertices).
Definition

Graph $G$ is \textit{$k$-almost embeddable} in surface $\Sigma$ if

- there is a set $X$ of at most $k$ apex vertices and
- a graph $G_0$ embedded in $\Sigma$, such that
- $G \setminus X$ can be obtained from $G_0$ by attaching vortices of width $k$ on disjoint disks $D_1, \ldots, D_k$. 

$k$-almost embeddable
Graph Structure Theorem

**Theorem [Robertson-Seymour]**

For every graph $H$, there is an integer $k$ and a surface $\Sigma$ such that every $H$-minor-free graph has a tree decomposition where every torso is $k$-almost embeddable in $\Sigma$.

Originally stated only combinatorially, algorithmic versions are known.

- Running time was improved from $n^{f(H)}$ to $f(H) \cdot n^{O(1)}$.
- Algorithm finds also an apex set of size at most $k$ for each torso.
Planar

H-Minor-Free

∪

Bounded Genus

∪

Planar

[figure by Felix Reidl]
Excluding cliques

What do we get by excluding small cliques?

- $K_3$-minor free: every torso is size $\leq 2$ (trees).
- $K_4$-minor free: every torso is size $\leq 3$ (series-parallel graphs).
- $K_5$-minor free: every torso is planar or $V_8$.
- $K_k$-minor free for $k \geq 6$: every torso is $k$-almost embeddable in some surface $\Sigma_k$. 
Algorithmic applications

**Theorem [Demaine, Hajiaghayi, Kawarabayashi 2005]**

For every graph $H$, there is a constant $c_H$ such that for any $k \geq 1$, every $H$-minor-free graph $G$ can be partitioned into $k + 1$ vertex sets $V_1, \ldots, V_{k+1}$ such that $G \setminus V_i$ has treewidth at most $c_H \cdot k$ for any $i$. Furthermore, such a partition can be found in polynomial time.

PTAS is immediate for e.g., Independent Set: Set $k := \lceil 1/\epsilon \rceil$ and find the partition. For every $i = 1, \ldots, k + 1$, compute the solution optimally for $G \setminus V_i$. There is one $i$ for which the solution is $k / (k + 1) \geq 1 - \epsilon$ times the optimum.
**Theorem [Demaine, Hajiaghayi, Kawarabayashi 2005]**

For every graph $H$, there is a constant $c_H$ such that for any $k \geq 1$, every $H$-minor-free graph $G$ can be partitioned into $k + 1$ vertex sets $V_1, \ldots, V_{k+1}$ such that $G \setminus V_i$ has treewidth at most $c_H \cdot k$ for any $i$. Furthermore, such a partition can be found in polynomial time.

PTAS is immediate for e.g., **Independent Set**:

- Set $k := \lceil 1/\epsilon \rceil$ and find the partition.
- For every $i = 1, \ldots, k + 1$, compute the solution optimally for $G \setminus V_i$.
- There is one $i$ for which the solution is $k/(k + 1) \geq 1 - \epsilon$ times the optimum.
Finding minors
### Finding minors

Finding minors

**H-minor testing**

Input: graph \( G \)
Find: a model of \( H \) in \( G \).

**Theorem**

\( H \)-minor testing for **planar** \( H \) can be solved in time \( f(H) \cdot n^{O(1)} \).

**Proof:**

- If \( G \) has treewidth \( \geq g(H) \), then it contains a large grid minor, hence contains \( H \).
- If \( G \) has treewidth \( < g(H) \), then e.g., Courcelle's Theorem can be invoked to check if \( G \) contains an \( H \)-minor.
Finding rooted minors

**Theorem [Robertson and Seymour]**

$H$-minor testing can be solved in time $f(H) \cdot n^3$.

Robertson and Seymour actually solved a more general problem:

**Rooted $H$-minor testing**

**Input:** graph $G$, a vertex $\rho(v) \in V(G)$ for every $v \in V(H)$.

**Find:** a model of $H$ in $G$ where the image of $v$ contains $\rho(v)$.

A very useful special case (let $H$ be a matching with $k$ edges):

**$k$-Disjoint Paths**

**Input:** graph $G$ with vertices $(s_1, t_1), \ldots, (s_k, t_k)$.

**Find:** vertex-disjoint paths $P_1, \ldots, P_k$

where $P_i$ connects $s_i$ and $t_i$. 
Algorithm for minor testing

A vertex $v \in V(G)$ is irrelevant if its removal does not change the answer to $H \leq G$.

Ingredients of minor testing by [Robertson and Seymour]

1. Solve the problem on bounded-treewidth graphs.
2. If treewidth is large, either find an irrelevant vertex or the model of a large clique minor.
3. If we have a large clique minor, then either we are done (if the clique minor is “close” to the roots), or a vertex of the clique minor is irrelevant.

By iteratively removing irrelevant vertices, eventually we arrive to a graph of bounded treewidth.
Planar $k$-Disjoint Paths

**$k$-Disjoint Paths**

Input: graph $G$ with vertices $(s_1, t_1), \ldots, (s_k, t_k)$.
Find: vertex-disjoint paths $P_1, \ldots, P_k$
where $P_i$ connects $s_i$ and $t_i$.

**Theorem [Adler et al. 2011]**

The **$k$-Disjoint Paths** problem on planar graphs can be solved in time $2^{2^{O(k)}} \cdot n^{O(1)}$. 
Planar $k$-Disjoint Paths

$k$-Disjoint Paths

Input: graph $G$ with vertices $(s_1, t_1), \ldots, (s_k, t_k)$.
Find: vertex-disjoint paths $P_1, \ldots, P_k$
where $P_i$ connects $s_i$ and $t_i$.

Theorem [Adler et al. 2011]

The $k$-DISJOINT PATHS problem on planar graphs can be solved in time $2^{2^{O(k)}} \cdot n^{O(1)}$.

Main argument:

- either treewidth is $2^{O(k)}$ and we can use standard algorithmic techniques of bounded treewidth graphs, or
- treewidth is $2^{\Omega(k)}$ and we can find an irrelevant vertex whose deletion does not change the problem.
Planar \( k \)-Disjoint Paths

**Theorem**

Every planar graph with treewidth at least \( 5k \) has a \( k \times k \) grid minor.
Planar $k$-Disjoint Paths

**Theorem**

If treewidth of a planar graph is $\Omega(k)$, then it contains the subdivision of a $k \times k$ wall.

![Diagram of a $k \times k$ wall](image)
Planar $k$-Disjoint Paths

**Theorem**

If treewidth of a planar graph is $\Omega(k)$, then it contains the subdivision of a $k \times k$ wall.

---

**Lemma** [Adler et al. 2011]

If a $2^{O(k)} \times 2^{O(k)}$ wall of a planar graph does not enclose any terminals, then the middle vertex of the wall is irrelevant to the $k$-disjoint paths problem.
Planar $k$-Disjoint Paths

**Theorem**
If treewidth of a planar graph is $\Omega(k)$, then it contains the subdivision of a $k \times k$ wall.

**Lemma [Adler et al. 2011]**
If a $2^{O(k)} \times 2^{O(k)}$ wall of a planar graph does not enclose any terminals, then the middle vertex of the wall is irrelevant to the $k$-disjoint paths problem.
Irrelevant vertices

Lemma [Adler et al. 2011]

If there are $2^{O(k)}$ concentric cycles in a planar graph not enclosing any terminals, then the innermost cycle is irrelevant to the $k$-disjoint paths problem.

Any solution can be rerouted to avoid the innermost cycle.
Well-quasi-ordering
Well-quasi-ordering

Definition
A partial order is a well-quasi-ordering if

1. There is no infinite antichain.
2. There is no infinite descending chain.
Well-quasi-ordering

Definition
A partial order is a **well-quasi-ordering** if
1. There is no infinite antichain.
2. There is no infinite descending chain.
A partial order is a **well-quasi-ordering** if

1. There is no infinite antichain.
2. There is no infinite descending chain.
Well-quasi-ordering

**Definition**

A partial order is a **well-quasi-ordering** if

1. There is no infinite antichain.
2. There is no infinite descending chain.

**Example:** the subgraph relation $\subseteq$ is **not** a well-quasi-ordering:
Well-quasi-ordering

Graph Minors Theorem

The minor relation $\leq$ is a well-quasi-ordering on finite graphs.

Some equivalent reformulations:

**Corollary**

If $G$ is minor closed, then $\overline{G}$ has a finite number of minimal elements.

**Corollary**

If $G$ is minor closed, then $G$ has a finite obstruction set $\mathcal{F} = \{H_1, \ldots, H_k\}$, i.e.,

$$G \in G \iff \forall H \in \mathcal{F}, H \not\leq G$$
Well-quasi-ordering

Corollary

If $G$ is minor closed, then $\overline{G}$ has a finite number of minimal elements.
Well-quasi-ordering

**Corollary**

If $G$ is minor closed, then $\overline{G}$ has a finite number of minimal elements.
Nonconstructive algorithms

Corollary

If $G$ is minor closed, then $G$ has a finite obstruction set $\mathcal{F} = \{H_1, \ldots, H_k\}$, i.e.,

$$G \in G \iff \forall H \in \mathcal{F}, H \not\leq G$$

As we have a $O(n^3)$ minor test algorithm for every $H_i \in \mathcal{H}$:

Theorem

If $G$ is minor closed, then there is a $O(n^3)$ time algorithm for recognizing graphs in $G$.

Examples:

- graphs that can be drawn on a torus (double torus etc.) form a minor-closed class: there is a $O(n^3)$ algorithm.
- graphs that have a linkless embedding in 3-space form a minor closed class: there is a $O(n^3)$ algorithm.
Applications

**Planar Face Cover:** Given a graph $G$ and an integer $k$, find an embedding of planar graph $G$ such that there are $k$ faces that cover all the vertices.
Planar Face Cover: Given a graph $G$ and an integer $k$, find an embedding of planar graph $G$ such that there are $k$ faces that cover all the vertices.

For every fixed $k$, the class $G_k$ of graphs of yes-instances is minor closed.

For every fixed $k$, there is a $O(n^3)$ time algorithm for Planar Face Cover.
Applications

**k-Leaf Spanning Tree:** Given a graph $G$ and an integer $k$, find a spanning tree with at least $k$ leaves.

Technical modification: Is there such a spanning tree for at least one component of $G$?
Applications

**k-Leaf Spanning Tree:** Given a graph $G$ and an integer $k$, find a spanning tree with at least $k$ leaves.

Technical modification: Is there such a spanning tree for at least one component of $G$?

For every fixed $k$, the class $G_k$ of no-instances is minor closed.

$\Downarrow$

For every fixed $k$, **k-Leaf Spanning Tree** can be solved in time $O(n^3)$. 

**Definition**

If $G$ is a graph property, then $G + k\text{v}$ contains graph $G$ if there is a set $S \subseteq V(G)$ of $k$ vertices such that $G \setminus S \in \mathcal{G}$. 

$G + k$ vertices
**Definition**

If $G$ is a graph property, then $G + kv$ contains graph $G$ if there is a set $S \subseteq V(G)$ of $k$ vertices such that $G \setminus S \in \mathcal{G}$.

**Observation**

If $G$ is minor closed, then $G + kv$ is minor closed for every fixed $k$.

$\Rightarrow$ It is (nonuniform) FPT to decide if $G$ can be transformed into a member of $\mathcal{G}$ by deleting $k$ vertices.
If $G$ is minor closed, then $G + kv$ is minor closed for every fixed $k$.

⇒ It is (nonuniform) FPT to decide if $G$ can be transformed into a member of $G$ by deleting $k$ vertices.

- If $G = \text{forests}$ ⇒ $G + kv =$ graphs that can be made acyclic by the deletion of $k$ vertices
  ⇒ Feedback Vertex Set is FPT.

- If $G = \text{planar graphs}$ ⇒ $G + kv =$ graphs that can be made planar by the deletion of $k$ vertices ($k$-apex graphs)
  ⇒ $k$-Apex Graph is FPT.

- If $G = \text{empty graphs}$ ⇒ $G + kv =$ graphs with vertex cover number at most $k$
  ⇒ Vertex Cover is FPT.
Nonconstructive algorithms

- The running time is beyond horrible.
- Quick tool for obtaining very general results.
- For many concrete problems, simpler and more efficient algorithms were found.
- Nonuniform FPT: a separate algorithm for every fixed $k$, rather than a single $f(k) \cdot n^{O(1)}$ algorithm.
Other containment relations
Topological subgraphs

Definition

Subdivision of a graph: replacing each edge by a path of length 1 or more.

Graph $H$ is a topological subgraph of $G$ (or topological minor of $G$, or $H \leq_T G$) if a subdivision of $H$ is a subgraph of $G$. 

\[ \leq_T \]
**Topological subgraphs**

**Definition**

**Subdivision** of a graph: replacing each edge by a path of length 1 or more.

Graph $H$ is a **topological subgraph** of $G$ (or **topological minor** of $G$, or $H \leq_T G$) if a subdivision of $H$ is a subgraph of $G$. 

![Diagram](image-url)
Topological subgraphs

**Definition**

**Subdivision** of a graph: replacing each edge by a path of length 1 or more.

Graph $H$ is a **topological subgraph** of $G$ (or **topological minor** of $G$, or $H \leq_T G$) if a subdivision of $H$ is a subgraph of $G$.

Equivalently, $H \leq_T G$ means that $H$ can be obtained from $G$ by removing vertices, removing edges, and dissolving degree two vertices.

A classical result

**Theorem [Kuratowski 1930]**
A graph $G$ is planar if and only if $K_5 \not\leq_T G$ and $K_{3,3} \not\leq_T G$.

**Theorem [Wagner 1937]**
A graph $G$ is planar if and only if $K_5 \not\leq G$ and $K_{3,3} \not\leq G$. 
Minors vs. subdivisions

Simple fact

If $H$ has max. degree $\leq 3$, then $H \leq G \iff H \leq_T G$. 
Minors vs. subdivisions

Simple fact

If $H$ has max. degree $\leq 3$, then $H \leq G \iff H \leq_T G$. 
Minors vs. subdivisions

Simple fact

For every $H$, there is a finite set $\mathcal{H}$ such that

$$H \leq G \iff \exists H' \in \mathcal{H} : H' \leq_T G.$$
Minors vs. subdivisions

Simple fact
For every $H$, there is a finite set $\mathcal{H}$ such that

$$H \leq G \iff \exists H' \in \mathcal{H} : H' \leq_T G.$$
Minors vs. subdivisions

Simple fact

For every $H$, there is a finite set $\mathcal{H}$ such that

$$H \leq G \iff \exists H' \in \mathcal{H} : H' \leq_T G.$$ 

- Every class that can be defined by excluding minors can be defined by excluding topological subgraphs.
- But the converse is not true: excluding a $K_{1,4}$ topological subgraph means that max. degree is $< 4$. 
Finding topological subgraphs

Deciding $H \leq_T G$:

- Guess the image of each $v \in V(H)$ in $G$.
- Solve the $k$-DISJOINT PATHS where $k = |E(H)|$ and the paths correspond to the edges of $H$ in $G$.

**Corollary**

We can decide in $n^{f(H)}$ time if $H \leq_T G$.

**Theorem [Grohe, Kawarabayashi, M., Wollan 2011]**

We can decide in $f(H) \cdot n^3$ time if $H \leq_T G$. 

Well-quasi-ordering (lack of)

The relation $\leq_T$ is not a well-quasi-ordering.
Torso of a bag: we make the intersections with the adjacent bags cliques.
**Torso**

**Torso of a bag:** we make the intersections with the adjacent bags cliques.
Structure theorems

Theorem [Grohe and M. 2012]

For every $H$, there is an integer $k \geq 1$ such that every $H$-subdivision free graph has a tree decomposition where the torso of every bag is either

- $K_k$-minor free or

- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree").

**Note:** there is an $f(H) \cdot n^{O(1)}$ time algorithm for computing such a decomposition.
Structure theorems

Theorem [Grohe and M. 2012]

For every $H$, there is an integer $k \geq 1$ such that every $H$-subdivision free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$ or
- has degree at most $k$ with the exception of at most $k$ vertices (“almost bounded degree”).

Note: there is an $f(H) \cdot n^{O(1)}$ time algorithm for computing such a decomposition.

Algorithmic applications

Theorem [Grohe and M. 2012]
For every $H$, there is an integer $k \geq 1$ such that every $H$-subdivision free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$ or
- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree").

General message:
If a problem can be solved both

- on (almost-) embeddable graphs and
- on (almost-) bounded degree graphs,
then these results can be raised to

- $H$-subdivision free graphs
without too much extra effort.
Partial Dominating Set

**Partial Dominating Set**

Input: graph $G$, integer $k$
Find: a set $S$ of at most $k$ vertices whose closed neighborhood has maximum size

**Theorem**

*Partial Dominating Set* can be solved in time $f(H, k) \cdot n^{O(1)}$ on $H$-subdivision free graphs.
Partial Dominating Set

Sketch:

- **Partial Dominating Set** can be solved in linear-time on bounded-degree graphs (the closed neighborhood has bounded size).

- **Partial Dominating Set** can be solved in linear-time on planar graphs (standard layering/treewidth arguments).

- With some extra work, we can generalize this to almost-bounded degree and almost-embeddable graphs.

- The structure theorem together with bottom-up dynamic programming gives an algorithm for $H$-subdivision free graphs.
Graph Isomorphism

Theorem [Luks 1982] [Babai, Luks 1983]
For every fixed $d$, Graph Isomorphism can be solved in polynomial time on graphs with maximum degree $d$.

Theorem [Ponomarenko 1988]
For every fixed $H$, Graph Isomorphism can be solved in polynomial time on $H$-minor free graphs.

Theorem [Grohe and M. 2012]
For every fixed $H$, Graph Isomorphism can be solved in polynomial-time on $H$-subdivision free graphs.

Note:
- Running time is $n^{f(H)}$, not FPT parameterized by $H$.
- Requires a more general “invariant acyclic tree-like decomposition.”
Immersions

Definition

Graph $H$ has an immersion in $G$ ($H \leq_{im} G$) if there is a mapping $\phi$ such that

- For every $v \in V(H)$, $\phi(v)$ is a distinct vertex in $G$.
- For every $xy \in E(H)$, $\phi(xy)$ is a path between $\phi(x)$ and $\phi(y)$, and all these paths are edge disjoint.

Note: $H \leq_T G$ implies $H \leq_{im} G$. 
Finding immersions:

**Theorem** [Grohe, Kawarabayashi, M., Wollan 2011]
We can decide in $f(H) \cdot n^3$ time if $H \leq im G$.

Well-quasi-ordering:

**Robertson and Seymour**
The immersion relation $\leq im$ is a well-quasi-ordering on finite graphs.

What about a structure theorem?
Excluding immersions

As excluding $K_k$-immersions implies excluding $K_k$ topological subgraphs, we get:

**Theorem [Grohe and M. 2012]**

For every $H$, there is an integer $k \geq 1$ such that every $H$-immersion free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$ or
- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree").
Excluding immersions

As excluding $K_k$-immersions implies excluding $K_k$ topological subgraphs, we get:

**Theorem** [Grohe and M. 2012]

For every $H$, there is an integer $k \geq 1$ such that every $H$-immersion free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$ or
- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree").

However, embeddability does not seem to be relevant for immersions: the following graph has large clique immersions.
Excluding immersions

As excluding $K_k$-immersions implies excluding $K_k$ topological subgraphs, we get:

**Theorem [Grohe and M. 2012]**

For every $H$, there is an integer $k \geq 1$ such that every $H$-immersion free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$ or
- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree").

However, embeddability does not seem to be relevant for immersions: the following graph has large clique immersions.

Can we omit the first case?
Excluding immersions

**Theorem [Wollan]**

If $K_k$ has no immersion in $G$, then $G$ has a “tree-cut decomposition” of adhesion at most $k^2$ such that each “torso” has at most $k$ vertices of degree at least $k^2$.

Tree cut decomposition: a partition of the vertex set in tree-like way.
Excluding immersions

**Theorem [Wollan]**

If $K_k$ has no immersion in $G$, then $G$ has a “tree-cut decomposition” of adhesion at most $k^2$ such that each “torso” has at most $k$ vertices of degree at least $k^2$.

Tree cut decomposition: a partition of the vertex set in tree-like way.
Odd minors

Definition

Graph $H$ is an odd minor of $G$ ($H \leq_{odd} G$) if $G$ has a 2-coloring and there is a mapping $\phi$ that maps each vertex of $H$ to a tree of $G$ such that

- $\phi(u)$ and $\phi(v)$ are disjoint if $u \neq v$,
- every edge of $\phi(u)$ is bichromatic,
- if $uv \in E(H)$, then there is a monochromatic edge between $\phi(u)$ and $\phi(v)$.

Example: $K_3$ is an odd minor of $G$ if and only if $G$ is not bipartite.
Odd minors

**Finding odd minors:**

**Theorem** [Kawarabayashi, Reed, Wollan 2011]

There is an $f(H) \cdot n^{O(1)}$ time algorithm for finding an odd $H$-minor.

**Structure theorem:**

**Theorem** [Demaine, Hajiaghayi, Kawarabayashi 2010]

For every $H$, there is an integer $k \geq 1$ such that every odd $H$-minor free graph has a tree decomposition where the torso of every bag is

- $k$-almost embeddable in a surface of genus at most $k$ or
- bipartite after deleting at most $k$ vertices ("almost bipartite")

**Consequence:**

**Theorem** [Demaine, Hajiaghayi, Kawarabayashi 2010]

For every fixed $H$, there is a polynomial-time 2-approximation algorithm for chromatic number on odd $H$-minor free graphs.
Odd subdivisions

**Definition**

**Odd subdivision** of a graph: replacing each edge by a path of odd length (1 or more).

If $G$ contains an odd $H$-subdivision, then $H \leq_T G$ and $H \leq_{\text{odd}} G$. 
Odd subdivisions

A structure theorem for excluding odd $H$-subdivision should be stronger than

- the structure theorem for excluded subdivisions ($k$-almost embeddable, almost bounded degree) and
- the structure theorem for excluded odd minors ($k$-almost embeddable, almost bipartite).
Odd subdivisions

A structure theorem for excluding odd $H$-subdivision should be stronger than

- the structure theorem for excluded subdivisions ($k$-almost embeddable, almost bounded degree) and
- the structure theorem for excluded odd minors ($k$-almost embeddable, almost bipartite).

**Theorem** [Kawarabayashi 2013]

For every $H$, there is an integer $k \geq 1$ such that every odd $H$-subdivision free graph has a tree decomposition where the torso of every bag is either

- $k$-almost embeddable in a surface of genus at most $k$,
- has degree at most $k$ with the exception of at most $k$ vertices ("almost bounded degree"), or
- bipartite after deleting at most $k$ vertices ("almost bipartite").
What did we learn, Palmer?

- Algorithms for bounded treewidth graphs: tedious, but elementary.
  (dynamic programming, Courcelle’s Theorem)
- Applications of bounded treewidth algorithms.
  (the shifting technique, bidimensionality, grid theorems)
- Generalization to bounded genus graphs.
- The structure theorem.
- Minor testing and well-quasi-ordering.
