## Variational Modeling

# Variational Modeling

## Basic Techniques

# Bayesian Approach

Candidate reconstruction  $S$  – 

Measured data  $D$  – 

# Calculus of Variation

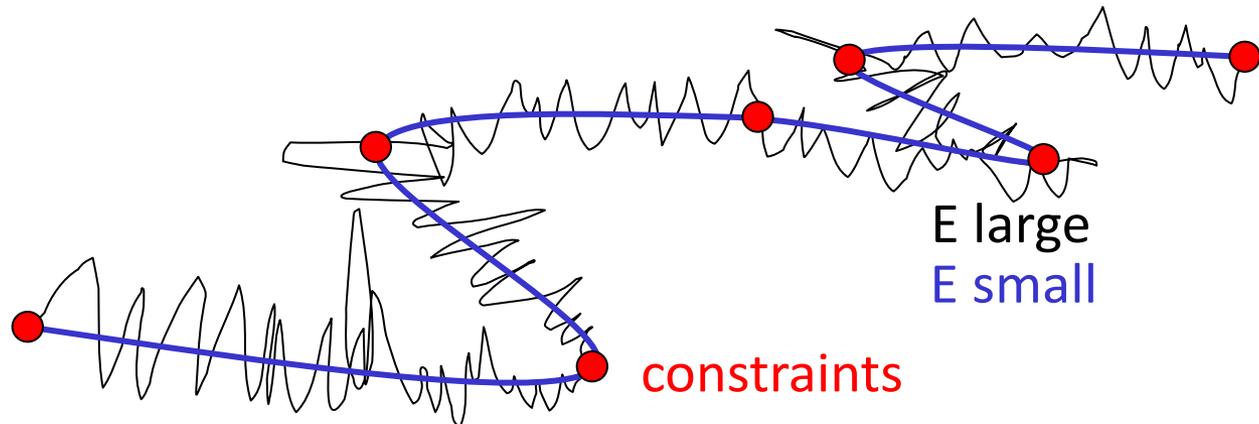

## Basic Idea:

- We look at a set of functions  $f: S \rightarrow D$
- We define an “*energy functional*”  $E: (S \rightarrow D) \rightarrow \mathbb{R}$ 
  - A *functional* assigns real numbers to functions
  - Each function gets a “score”
  - “Energy” means: the smaller the better
- We set up additional requirements (“constraints”) on  $f$ .
  - *Soft constraints*  $\rightarrow$  violation increases energy.
  - *Hard constraints*  $\rightarrow$  violation not allowed.
- We then compute the function(s)  $f$  that minimize  $E$ .

# Calculus of Variation

## Very general framework:

- A lot of problems can be directly formulated as variational problems.
- Example 1:
  - We are looking for a curve.
  - It should be as smooth as possible (energy = non-smoothness).
  - It should go through a number of points (hard constraints).

# Calculus of Variation

## Another example:

- **Problem:** We want to go to the moon.
- **Given:**
  - Orbits of moons, planets and star(s).
  - Flight conditions (atmosphere, gravitation of stellar bodies)
- **Unknowns:**
  - Throttle (magnitude, direction) from rocket motors (vector function)
- **Energy function:**
  - Usage of rocket fuel (the fewer the better)
  - Perhaps: Overall travel time (maybe not longer than a week)

# Calculus of Variation

## To the moon:

- **Constraints:**

- We want to start in Cape Canaveral (upright trajectory) and end up on the moon.
- We do not want to hit moons or planets on our way.
- We want to approach the moon at no more than 20 km/h relative speed upon touchdown.
- The rocket motor has a limited range of forces it can create (not more than a certain thrust, no backward thrust)

**So flying to the moon is just minimizing a functional.**

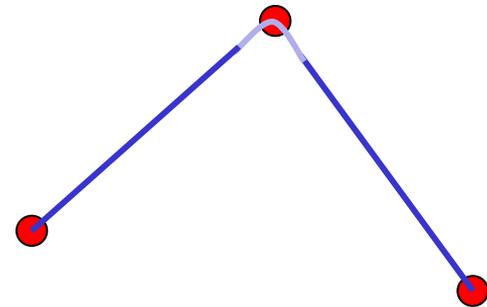

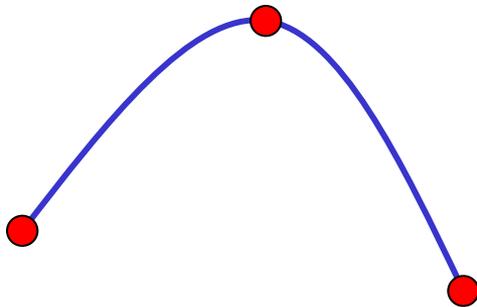

(ok, this is slightly simplified)

# A Simple Example

## Simple example: variational splines

- Energy:
  - We want smooth curves
  - Smooth translates to minimum curvature
  - Quadratic penalty:

$$E(f) = \int_{\text{curve}} |\text{curvature}_f(t)|^2 dt$$

# A Simple Example

## Simple example: variational splines

- Energy:
  - Problem: curvature is non-linear
  - Easier to minimize: second derivatives

$$E(f) = \int_{\text{curve}} \left[ \frac{d^2}{dt^2} \mathbf{f}(t) \right]^2 dt$$

# A Simple Example

## Simple example: variational splines

- Soft constraints
  - Parameter values  $t_1, \dots, t_n$  at which we should approximate points  $\mathbf{p}_1, \dots, \mathbf{p}_n$ :

$$E(f) = \int_{t=t_1}^{t_n} \left[ \frac{d^2}{dt^2} \mathbf{f}(t) \right]^2 dt + \lambda \sum_{i=1}^n (\mathbf{f}(t_i) - \mathbf{p}_i)^2$$

- $\lambda$  controls (lack of) smoothness.

# A Simple Example

## Simple example: variational splines

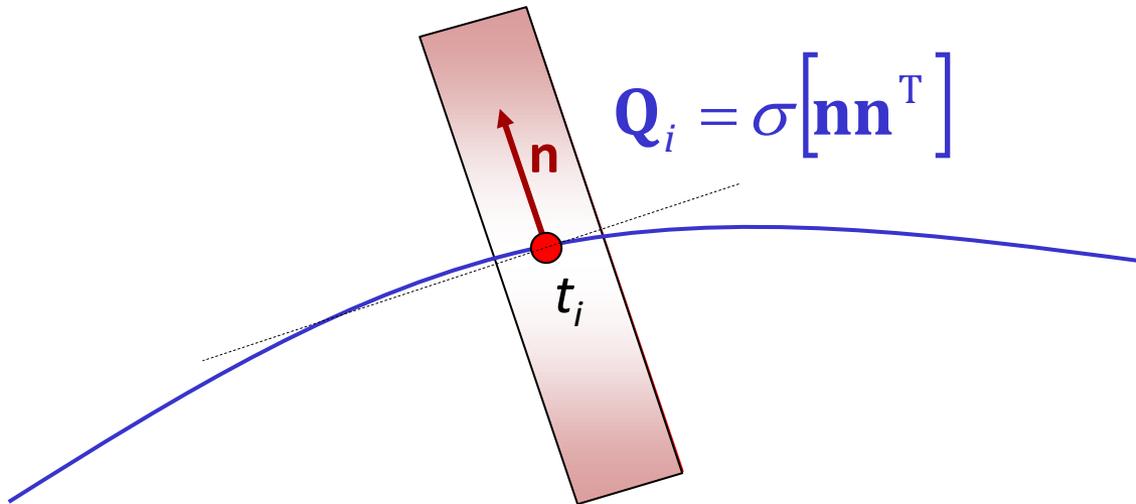

- Soft constraints
  - Specify the accuracy by error quadrics  $\mathbf{Q}_1, \dots, \mathbf{Q}_n$ :

$$E(f) = \int_{t=t_1}^{t_n} \left[ \frac{d^2}{dt^2} \mathbf{f}(t) \right]^2 dt + \sum_{i=1}^n (\mathbf{f}(t_i) - \mathbf{p}_i)^T \mathbf{Q}_i (\mathbf{f}(t_i) - \mathbf{p}_i)$$

# Rank-Deficient Quadrics

## The rank deficient error quadric trick:

- A rank-1 matrix constraints the curve in one direction only
- E.g.: Point-to-surface constraints

# Numerical Treatment

## Numerical computation:

- No closed form solution
  - Discretize (finite dimensional function space)
  - Solve for coefficients (coordinate vector in this function space)

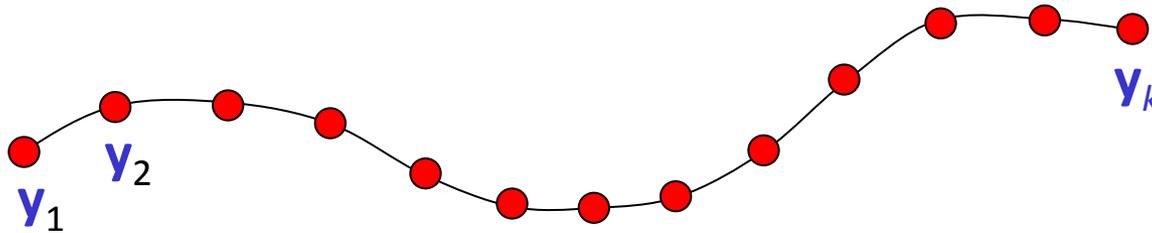

# Finite Differences

## FD solution:

- Represent curve as array of  $k$  values:

|     |       |       |       |     |          |          |
|-----|-------|-------|-------|-----|----------|----------|
| $t$ | 0     | 0.1   | 0.2   | ... | 7.4      | 7.5      |
| $y$ | $y_0$ | $y_1$ | $y_2$ | ... | $y_{74}$ | $y_{75}$ |

- Unknowns are the curve points  $y_1, \dots, y_k$

# Discretized Energy Function

## Discretized Energy Function:

- Energy is a squared linear expression
  - Quadratic discrete objective function
- Constraints are quadratic by construction
- Solution by linear system

$$E(f) = \int_{t=t_1}^{t_n} \left[ \frac{d^2}{dt^2} \mathbf{f}(t) \right]^2 dt + \sum_{i=1}^n (\mathbf{f}(t_i) - \mathbf{p}_i)^T \mathbf{Q}_i (\mathbf{f}(t_i) - \mathbf{p}_i)$$

$$E^{(discr)}(f) = \sum_{i=1}^k \left[ \frac{\mathbf{y}_{i-1} - 2\mathbf{y}_i + \mathbf{y}_{i+1}}{h^2} \right]^2 + \sum_{i=1}^n (\mathbf{y}_{index(t_i)} - \mathbf{p}_i)^T \mathbf{Q}_i (\mathbf{y}_{index(t_i)} - \mathbf{p}_i)$$

(neglected here: handling boundary values)

# Summary

## Summary:

- Variational approaches look like this:

compute  $\operatorname{argmin}_{f \in F} E(f)$ ,

$$E(f) = E^{(data)}(f) + E^{(regularizer)}(f),$$

$$f \in F = \{f \mid f \text{ satisfies hard constraints}\}$$

- Connection to statistics:
  - Bayesian maximum a posteriori estimation
  - $E^{(data)}$  is the data likelihood (log space)
  - $E^{(regularizer)}$  is a prior distribution (log space)

# Variational Toolbox

Data Fitting, Regularizer Functionals,  
Discretizations

# Toolbox

## In the following:

- We will discuss...
  - ...useful standard functionals.
  - ...how to model soft constraints.
  - ...how to model hard constraints.
  - ...how to discretize the model.
- Then snap & click your favorite custom variational modeling scheme.
- (Click & snap means: add together to a composite energy)

# Functionals

# Functionals

## Standard Functional #1: Function norm

- Given a function  $\mathbf{f}: \mathbb{R}^m \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(zero)}(f) = \int_{\Omega} \mathbf{f}(\mathbf{x})^2 d\mathbf{x}$$

- Function values should not become too large
- Often useful to avoid numerical problems
  - Adding  $\lambda E^{(zero)}$  to quadratic energy:  
smallest eigenvalue bounded by  $\lambda$  ( $\rightarrow$  condition number)
  - System always solvable

# Functionals

## Standard Functional #2: Harmonic energy

- Given a function  $\mathbf{f}: \mathbb{R}^m \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

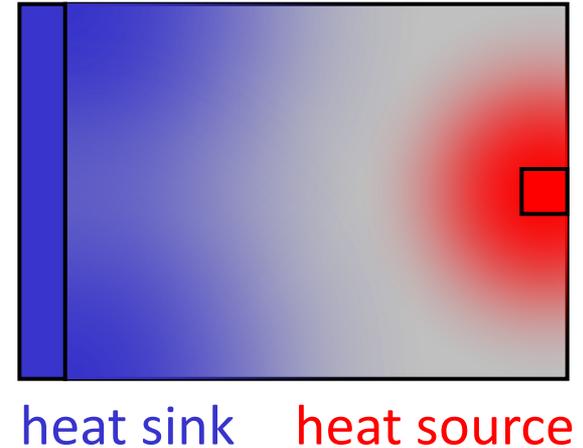

$$E^{(\text{harmonic})}(f) = \int_{\Omega} (\nabla \mathbf{f}(\mathbf{x}))^2 d\mathbf{x}$$

- Differences to neighboring points as small as possible
- Appears all the time in physics & engineering

# Harmonic Energy

## Example: Heat equation

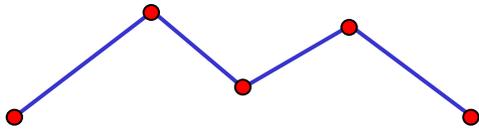

- Metal plate
- Hard constraints:
  - Heat source
  - Heat sink
- Final heat distribution?
  - Heat flow tends to equalize temperature.
    - Stronger heat flow for larger temperature gradients.
  - Gradients become as small as possible.

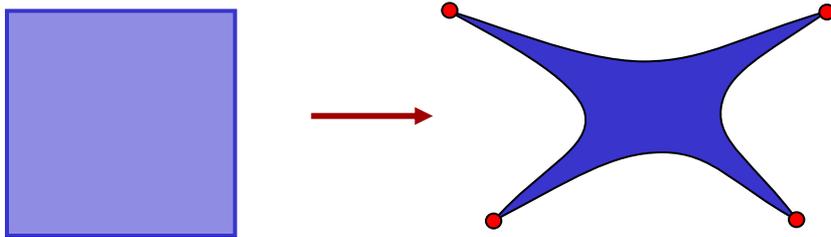

# Harmonic Energy

## Example: Harmonic energy

- Curves that minimize the harmonic energy:
  - Shortest path, a.k.a. polygons

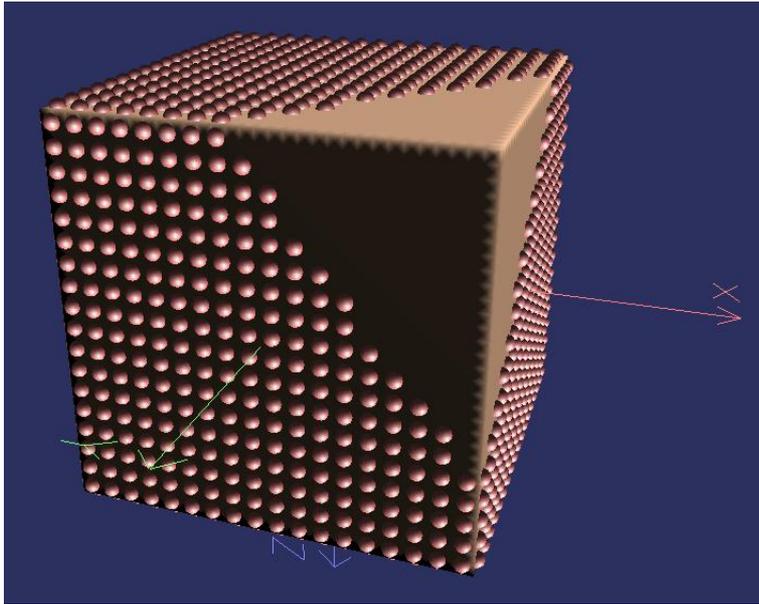

- Two-dimensional parametric surface:

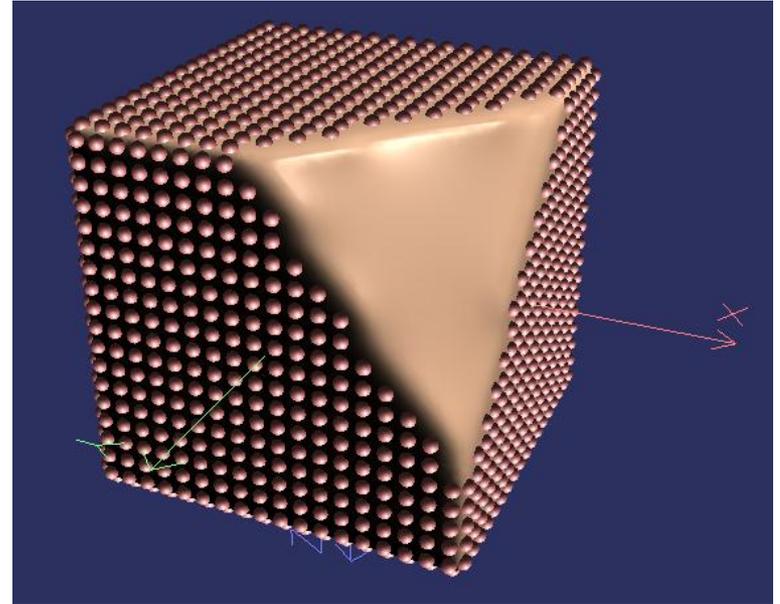

# Surface Example

## Surface fitting with Laplacian Regularizer:

initialization

result

**Data attraction:** point-to-plane, Gaussian window  
**Regularizer:** minimize triangle edge length

# Functionals

## Standard Functional #3: Thin plate spline energy

- Given a function  $\mathbf{f}: \mathbb{R}^m \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

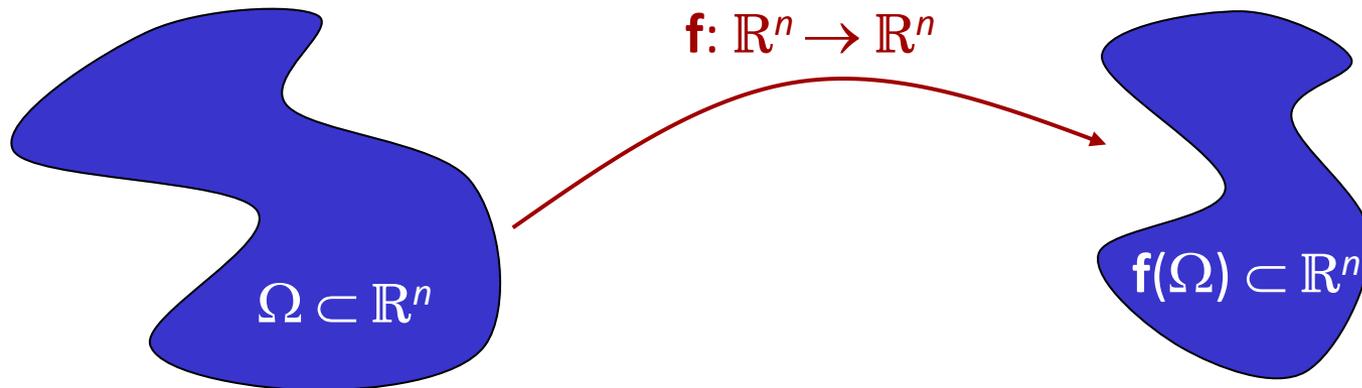

$$E^{(TSS)}(\mathbf{f}) = \int_{\Omega} \sum_{i=1}^m \sum_{j=1}^m \left( \left\| \frac{\partial^2}{\partial x_i \partial x_j} \mathbf{f}(\mathbf{x}) \right\|^2 \right) d\mathbf{x}$$

- Objective: minimize integral second derivatives (approx. curvature)
- “Be smooth”:
  - Yields smooth curves & surfaces
  - A true curvature based energy is rarely used (non-quadratic)

# Energies for Vector Fields

## Vector fields:

- Now consider volume deformations:  $\mathbb{R}^n \rightarrow \mathbb{R}^n$
- Think of an object moving (over time).
  - $\mathbf{f}(\mathbf{x})$  describes its deformation.
  - $\mathbf{f}(\mathbf{x}, t)$  describes its motion over time.

# Functionals

## Standard Functional #4: Green's deformation tensor

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(deform)}(\mathbf{f}) = \int_{\Omega} \left\| \mathbf{M} [\nabla \mathbf{f}^T \nabla \mathbf{f} - \mathbf{I}] \right\|_F^2 d\mathbf{x}$$

- Objective: minimize metric distortion
  - First fundamental form
- Physically-based deformation modeling:
  - Invariant under rigid transformations.
  - Bending, scaling, shearing is penalized.
  - Energy is non-quadratic (4-th order).
  - 9×9 Matrix  $\mathbf{M}$  encodes material properties (often  $\mathbf{M} = \mathbf{I}$ ).

# Functionals

## Standard Functional #5: Volume preservation

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(volume)}(\mathbf{f}) = \int_{\Omega} [\det(\nabla \mathbf{f}) - 1]^2 d\mathbf{x}$$

- Objective: minimize local volume changes
- This energy tries to preserve the volume at any point.
  - Incompressible materials (for example fluids)
  - Invariant under rigid transformations
  - Non-quadratic (6th-order in 3D)

# Functionals

## Standard Functional #6: Infinitesimal volume preservation

- Velocity  $\mathbf{v}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$

- Minimize:

$$E^{(volume)}(\mathbf{v}) = \int_{\Omega} (\operatorname{div} \mathbf{v}(\mathbf{x}))^2 d\mathbf{x} = \int_{\Omega} \left( \frac{\partial}{\partial x_1} \mathbf{v}(\mathbf{x}) + \dots + \frac{\partial}{\partial x_n} \mathbf{v}(\mathbf{x}) \right)^2 d\mathbf{x}$$

- Objective: minimize local volume changes in a velocity field
- Difference to the previous case:
  - The vectors are instantaneous motions ( $\mathbf{v}(\mathbf{x}) = d/dt \mathbf{f}(\mathbf{x}, t)$ )
  - A divergence free (time dependent) vector field will not introduce volume changes
  - Linear, but works only for small time steps
  - Large (rotational) displacements are not covered

# Functionals

## Standard Functionals #7 & #8: Velocity & acceleration

- Given a function  $\mathbf{v}: (\mathbb{R}^n \times \mathbb{R}) \supset \Omega \rightarrow \mathbb{R}^n$

- Minimize:

$$E^{(velocity)}(\mathbf{f}) = \iint_{\Omega} \left( \frac{d}{dt} \mathbf{f}(\mathbf{x}, t) \right)^2 dx dt, \quad E^{(acc)}(\mathbf{f}) = \iint_{\Omega} \left( \frac{d^2}{dt^2} \mathbf{f}(\mathbf{x}, t) \right)^2 dx dt$$

- Objective: minimize velocity / acceleration
- Models air resistance, inertia.

# Soft Constraints

# Soft Constraints

## Penalty functions

- Uniform
- General quadrics
- Differential constraints

## Types of soft constraints

- Point-wise constraints
- Line / area constraints

## Constraint functions

- Least-squares
- M-estimators

# Uniform Soft Constraints

## Uniform, point-wise soft constraints:

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(constr)}(\mathbf{f}) = \sum_{i=1}^n q_i (\mathbf{f}(\mathbf{x}_i) - \mathbf{y}_i)^2$$

constraint weights (certainty)

prescribed values  $(\mathbf{x}, \mathbf{y})_i$

# Uniform Soft Constraints

## General quadratic, point-wise soft constraints:

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(constr)}(\mathbf{f}) = \sum_{i=1}^n (\mathbf{f}(\mathbf{x}_i) - \mathbf{y}_i)^T \mathbf{Q}_i (\mathbf{f}(\mathbf{x}_i) - \mathbf{y}_i)$$

constraint weights (general quadratic form, non-negative)

prescribed values  $(\mathbf{x}, \mathbf{y})_i$

# Uniform Soft Constraints

## Differential constraints:

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(constr)}(\mathbf{f}) = \sum_{i=1}^n \left( D\mathbf{f}(\mathbf{x}_i) - (D\mathbf{y})_i \right)^T \mathbf{Q}_i \left( D\mathbf{f}(\mathbf{x}_i) - (D\mathbf{y})_i \right)$$

constraint weights (general quadratic form, non-negative)

prescribed values  $(\mathbf{x}, D\mathbf{y})_i$

Differential operator:  $D = \begin{pmatrix} \frac{\partial}{\partial x_{i_1,1}} \dots \partial x_{i_{k_1},1} \\ \vdots \\ \frac{\partial}{\partial x_{i_1,m}} \dots \partial x_{i_{k_m},m} \end{pmatrix}$

This is still a quadratic constraints ( $\rightarrow$  linear system).

# Examples

## Examples of differential constraints:

- Prescribe normal orientation of a surface

$$\mathbf{f} : \mathbb{R}^2 \rightarrow \mathbb{R}^3, \quad E^{(constr)}(\mathbf{f}) = q \left( \begin{pmatrix} -\partial_u \\ -\partial_v \\ 1 \end{pmatrix} \mathbf{f} - \mathbf{n} \right)^2$$

- Prescribe rotation of a deformation field

$$\mathbf{f} : \mathbb{R}^3 \rightarrow \mathbb{R}^3, \quad E^{(constr)}(\mathbf{f}) = q \|\nabla \mathbf{f} - \mathbf{R}\|_F^2$$

- Prescribe velocity or acceleration of a particle trajectory

$$\mathbf{f} : \mathbb{R}^3 \times \mathbb{R} \rightarrow \mathbb{R}^3, \mathbf{f}(\mathbf{x}, t) = \mathbf{pos}, \quad E^{(constr)}(\mathbf{f}) = q(x, t) \left( \dot{\mathbf{f}}(\mathbf{x}, t) - \mathbf{a}(\mathbf{x}, t) \right)^2$$

# Line / Area Soft Constraints

## Line and area constraints:

- Given a function  $\mathbf{f}: \mathbb{R}^n \supset \Omega \rightarrow \mathbb{R}^n$
- Minimize:

$$E^{(constr)}(\mathbf{f}) = \int_{A \subseteq \Omega} (\mathbf{f}(\mathbf{x}) - \mathbf{y}(\mathbf{x}))^T \mathbf{Q}(\mathbf{x}) (\mathbf{f}(\mathbf{x}) - \mathbf{y}(\mathbf{x}))$$

quadratic error weights (may be position dependent)

prescribed values  $\mathbf{y}(\mathbf{x})$  (function of position  $\mathbf{x}$ )

area  $A \subseteq \Omega$  on which the constraint is placed (line, area, volume...)

- A.k.a: “transfinite constraints”

# Constraint Functions

## Constraint Functions:

- Typical: quadratic constraints  $E(x) = f(x)^2$ 
  - Easy to optimize (linear system)
  - Well-defined critical point (gradient vanishes)
  - However: sensitive to outliers
- Alternatives for bad data:
  - $L_1$ -norm constraints ( $E(x) = |f(x)|$ )
    - more robust
    - still convex, i.e. can be optimized
  - Truncated constraints
    - even more robust
    - non-convex, difficult to optimize

# Discretization

# Finite Element Discretization

## Finite-element discretization:

- Finite dimensional space spanned by basis functions
- Finite differences (FD)
  - Special case
  - Grid of piecewise constant basis
- General approach:

$$\operatorname{argmin}_f E(f) \rightarrow \operatorname{argmin}_\lambda E(\tilde{f}_\lambda)$$

$$\tilde{f}_\lambda(x) = \sum_{i=1}^k \lambda_i b_i(x)$$

# Finite Element Discretization

## Derive a discrete equation:

- Just plug in the discrete  $\tilde{f}$ .
- Then minimize the it over the  $\lambda$ .
- Compute the critical point(s):

$$E(\tilde{f}_\lambda(x)) \rightarrow \min$$

$$\Rightarrow \forall i = 1 \dots k : \frac{\partial}{\partial \lambda_i} E(\tilde{f}_\lambda(x)) = 0$$

- Quadratic functionals: linear system.
- Non-linear, smooth functionals:  
Newton, Gauss-Newton, LBFGS, or the similar

# Example

---

## **(Abstract) example:**

- Minimize square integral of a differential operator
- Quadratic differential constraints
- Yields quadratic optimization problem in the coefficients

# Example

## (Abstract) example (cont):

$$E(f) = \int_{\Omega} \left( D^{(1)} f(x) \right)^2 dx + \mu \sum_{i=1}^n \left( D^{(2)} f(x_i) - y_i \right)^2$$

$$\tilde{f}_{\lambda}(x) = \sum_{i=1}^k \lambda_i b_i(x)$$

$$E(\tilde{f}_{\lambda}) = \int_{\Omega} \left( D^{(1)} \sum_{i=1}^k \lambda_i b_i(x) \right)^2 dx + \mu \sum_{i=1}^n \left( D^{(2)} \sum_{i=1}^k \lambda_i b_i(x) - y_i \right)^2$$

$$= \int_{\Omega} \left( \sum_{i=1}^k \lambda_i [D^{(1)} b_i](x) \right)^2 dx + \mu \sum_{i=1}^n \left( \sum_{i=1}^k \lambda_i D^{(2)} b_i(x) - y_i \right)^2$$

$$= \sum_{i=1}^k \sum_{j=1}^k \lambda_i \lambda_j \int_{\Omega} [D^{(1)} b_i](x) [D^{(1)} b_j](x) dx + \mu \sum_{i=1}^n \left( \sum_{i=1}^k \lambda_i D^{(2)} b_i(x) - y_i \right)^2$$

# Numerical Aspects

# How to solve the problems?

## Solving the discretized variational problem:

- Quadratic energy and quadratic constraints:
  - The discretization is a quadratic function as well.
  - The gradient is a linear expression.
  - The matrix in this expression is symmetric.
  - If the problem is well-defined, the matrix is semi-positive definite.
  - It is usually very sparse (coefficients of basis functions only interact with their neighbors, as far as their support overlaps).
  - We can use iterative sparse system solvers:
    - Most frequently used: conjugate gradients (needs SPD matrix). CG is available in GeoX.

# How to solve the problems?

## Solving the discretized variational problem:

- Non linear energy functions:
  - If the function is convex, we can get to a critical point that is the global minimum.
  - In general, we can only find a local optimum (or critical point).
    - Need a *good initialization*
  - **Newton optimization:**
    - 2nd order Taylor expansions (Hessian matrix, gradient)
    - Iteratively solve linear problems.
    - Typically, Hessian matrices are sparse. Use conjugate gradients to solve for critical points.
  - **Non-linear conjugate gradients:** with line search (faster than simple gradient decent).
  - **LBFGS:** Black box-solver, only needs gradient.

# Hard Constraints

# Hard Constraints

## Hard Constraints:

- Properties of the solution to be met *exactly*
- Three options to implement hard constraints:
  - Strong soft constraints (easy, but not exact)
  - Variable elimination (exact, but limited)
  - Lagrange multipliers (most complex and general method)

# Hard Soft Constraints

## Simplest Implementation:

- Soft constraints with large weight

$$E(f) = E^{(\text{regularizer})}(f) + \lambda E^{(\text{constraints})}(f), \text{ with } \lambda \text{ very large (say } 10^6)$$

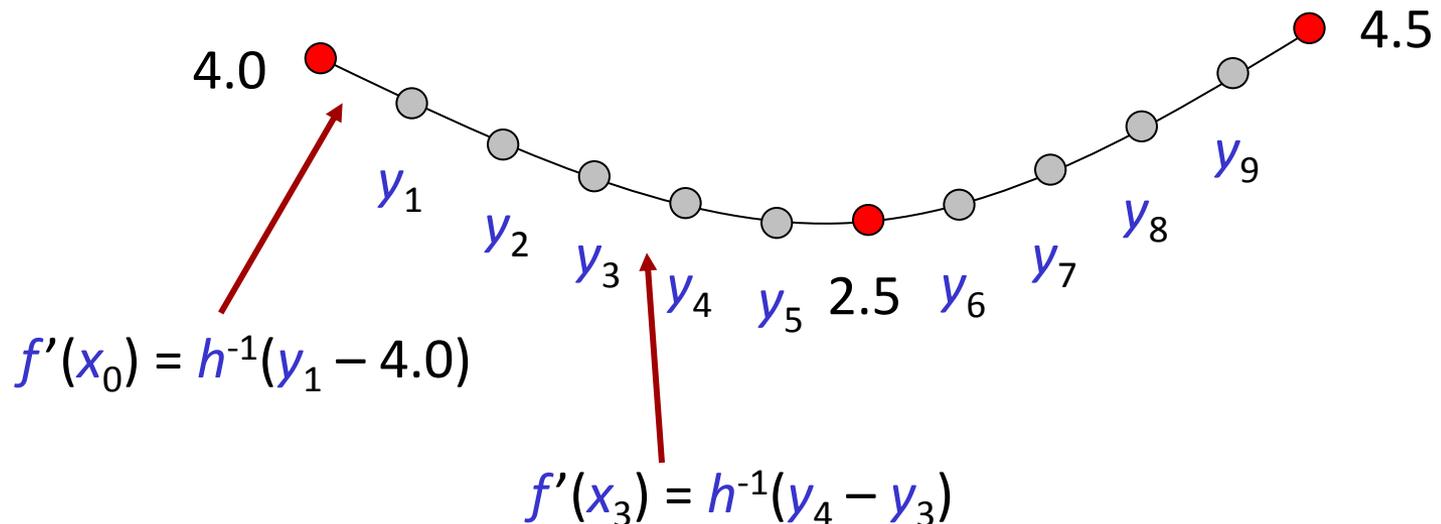

- A few serious problems:
  - Technique is not exact
    - Might be not acceptable for some applications
  - The stronger the constraints, the larger the weight. This means:
    - The condition number of the quadric matrix (condition of the Hessian in the non-linear case) becomes worse.
    - At some point, no solution is possible anymore.
    - Iterative solvers are slowed down (e.g. conjugate gradients)

# Variable Elimination

## Idea: Variable elimination

- We just replace variables by fixed numbers.
- Then solve the remaining system.

## Example:

# Variable Elimination

## Advantages:

- Exact constraints
- Conceptually simple

## Problems:

- Only works for simple constraints (variable = value)
- Need to augment system
  - Not easy to implement generically
- Does not work for FE methods (general basis functions)
  - Values are *sum* of scaled basis functions

# Lagrange Multipliers

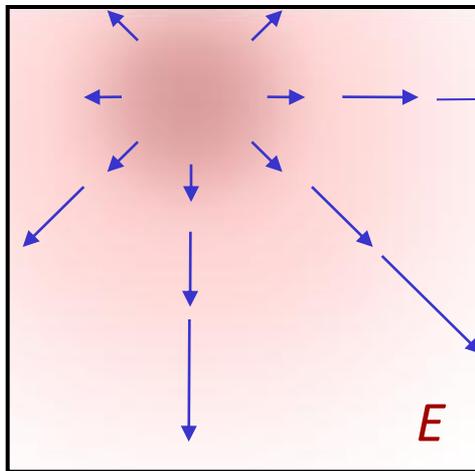

## **Most general technique:** Lagrange multipliers

- Works for complex, composite constraints
- General basis functions
- Exact solutions (no approximation)

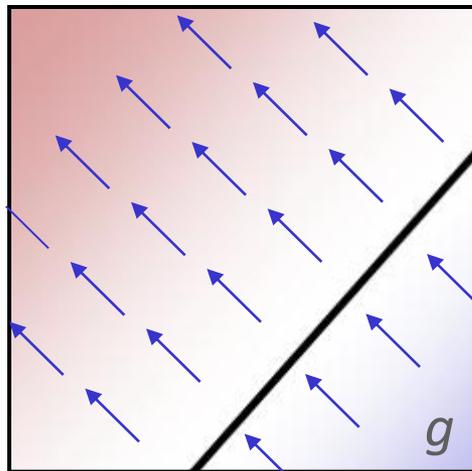

# Lagrange Multipliers

Here is the idea:

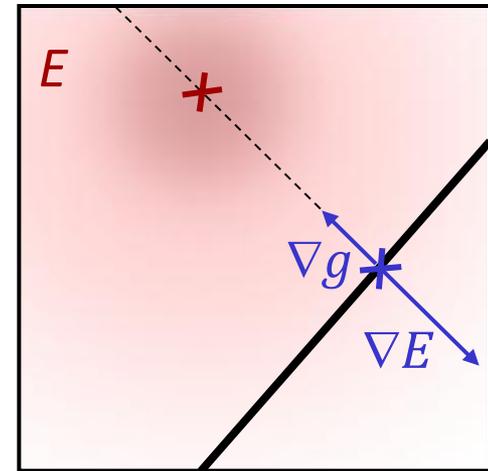

- Assume we want to optimize  $E(x_1, \dots, x_n)$  subject to an implicitly formulated constraint  $g(x_1, \dots, x_n) = 0$ .
- This looks like this:

$\nabla E$

$\nabla g$

$\nabla E = \lambda \nabla g, g(\mathbf{x}) = 0$

# Lagrange Multipliers

## Formally:

- Optimize  $E(x_1, \dots, x_n)$  subject to  $g(x_1, \dots, x_n) = 0$ .
- Formally, we want:

$$\nabla E(\mathbf{x}) = \lambda \nabla g(\mathbf{x}) \text{ and } g(\mathbf{x}) = 0$$

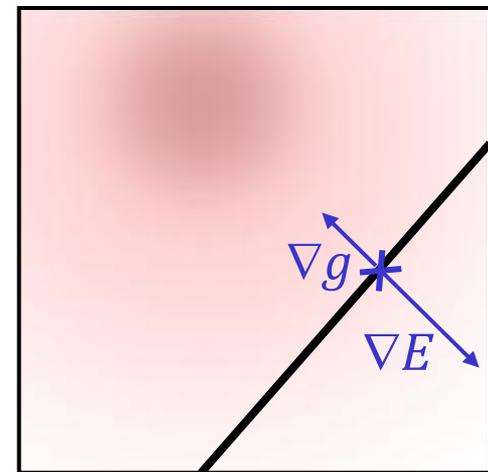

- We get a local optimum for:

$$LG(\mathbf{x}) = E(\mathbf{x}) + \lambda g(\mathbf{x})$$

$$\nabla_{\mathbf{x}, \lambda} LG(\mathbf{x}) = 0$$

$$\text{i.e.: } \left( \partial_{x_1}, \dots, \partial_{x_n}, \partial_{\lambda} \right) LG(\mathbf{x}) = 0$$

- A critical point of this equation satisfies both  $\nabla E(\mathbf{x}) = \lambda \nabla g(\mathbf{x})$  and  $g(\mathbf{x}) = 0$ .

$$\nabla E = \lambda \nabla g$$

# Example

**Example:** Optimizing a quadric subject to a linear equality constraint

- We want to optimize:  $E(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b} \mathbf{x}$
- Subject to:  $g(\mathbf{x}) = \mathbf{m} \mathbf{x} + n = 0$

**We obtain:**

- $LG(\mathbf{x}) = E(\mathbf{x}) + \lambda g(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b} \mathbf{x} + \lambda(\mathbf{m} \mathbf{x} + n)$   
 $\nabla_{\mathbf{x}}(LG(\mathbf{x})) = 2\mathbf{A} \mathbf{x} + \mathbf{b} + \lambda \mathbf{m}$   
 $\nabla_{\lambda}(LG(\mathbf{x})) = \mathbf{m} \mathbf{x} + n$
- Linear system: 
$$\begin{pmatrix} 2\mathbf{A} & \mathbf{m} \\ \mathbf{m}^T & 0 \end{pmatrix} \begin{pmatrix} \mathbf{x} \\ \lambda \end{pmatrix} = \begin{pmatrix} -\mathbf{b} \\ -n \end{pmatrix}$$

# Multiple Constraints

## Multiple Constraints:

- Similar idea
- Introduce multiple “Lagrange multipliers”  $\lambda$ .

$$E(x) \rightarrow \min$$

$$\text{subject to: } \forall i = 1 \dots k : g_i(x) = 0$$

Lagrangian objective function:

$$LG(\mathbf{x}) = E(\mathbf{x}) + \sum_{i=1}^k \lambda_i g_i(\mathbf{x})$$

$$\nabla_{\mathbf{x}, \lambda} LG(\mathbf{x}) = 0$$

$$\text{i.e.: } \left( \partial_{x_1}, \dots, \partial_{x_n}, \partial_{\lambda_1}, \dots, \partial_{\lambda_k} \right) LG(\mathbf{x}) = 0$$

# Multiple Constraints

## Example: Linear subspace constraints

- $E(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b} \mathbf{x}$  subject to  $g(\mathbf{x}) = \mathbf{M} \mathbf{x} + \mathbf{n} = \mathbf{0}$
- $LG(\mathbf{x}) = E(\mathbf{x}) + \sum_{i=1}^n \lambda_i \mathbf{g}_i(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b} \mathbf{x} + \sum_{i=1}^n \lambda_i (\mathbf{m}_i \mathbf{x} + n_i)$
- Linear system: 
$$\begin{pmatrix} 2\mathbf{A} & \mathbf{M}^T \\ \mathbf{M} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \mathbf{x} \\ \boldsymbol{\lambda} \end{pmatrix} = \begin{pmatrix} -\mathbf{b} \\ -\mathbf{n} \end{pmatrix}$$
- Remark:  $\mathbf{M}$  must have full rank for this to work.

# What can we do with this?

## Multiple linear equality constraints:

- Constraint multiple function values, differential properties, integral values
- Area constraints: Sample at each basis function of the discretization and prescribe a value
- Need to take care:
  - We need to make sure that the constraints are linearly independent at any time

## Inequality constraints:

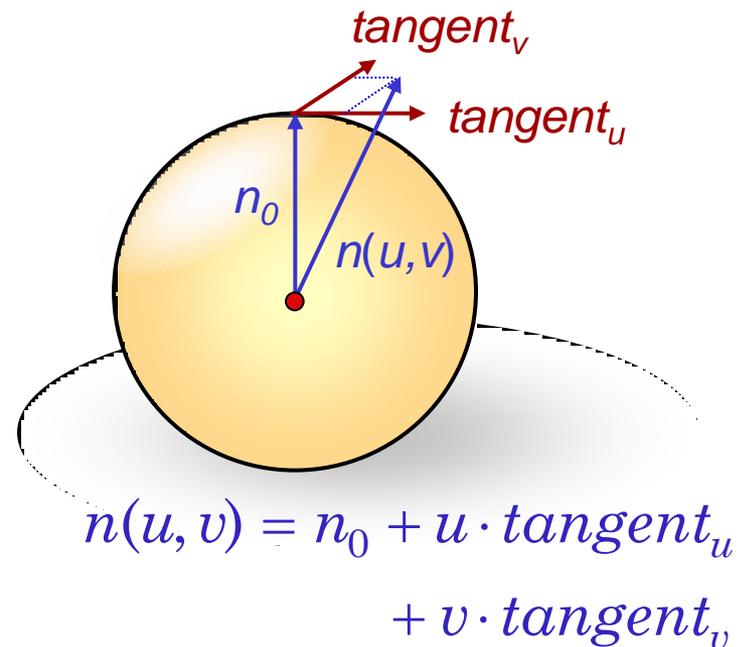

- There are efficient quadratic programming algorithms. (Idea: turn on and off the constraints intelligently.)

# Manifold Constraints

# Optimization on Unit Sphere

## Solution: Local Parameterization

- Current normal estimate
- Tangent parameterization
- New variables  $u, v$
- Renormalize
- Non-linear optimization
- No degeneracies

[Hoffer et al. 04]

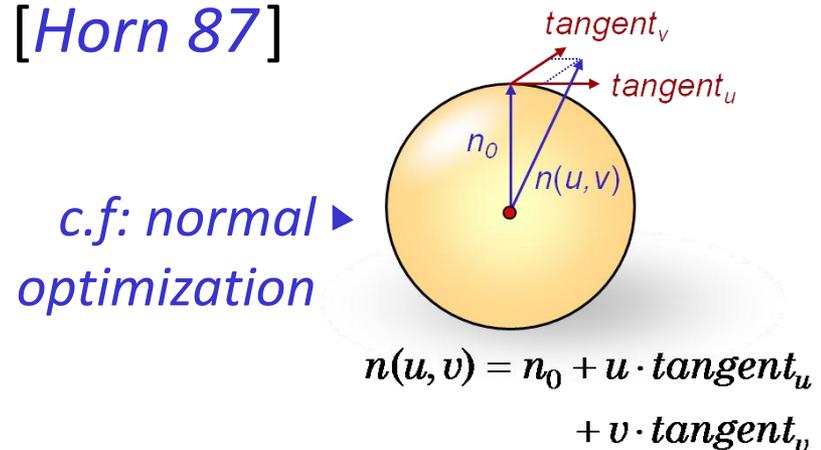

# Optimization on SO(3)

## Orthonormal matrices

- Local, 1st order, non-degenerate parametrization:

$$\mathbf{C}_{\mathbf{x}_i}^{(t)} = \begin{pmatrix} 0 & \alpha & \beta \\ -\alpha & 0 & \gamma \\ -\beta & -\gamma & 0 \end{pmatrix} \quad \begin{aligned} \mathbf{A}_i &= \mathbf{A}_0 \exp(\mathbf{C}_{\mathbf{x}_i}) \\ &\doteq \mathbf{A}_0 (I + \mathbf{C}_{\mathbf{x}_i}^{(t)}) \end{aligned}$$

- Optimize parameters  $\alpha, \beta, \gamma$ , then recompute  $\mathbf{A}_0$
- Compute initial estimate using [*Horn 87*]

# The Euler Lagrange Equation

(some more math)

# The Euler-Lagrange Equation

## Theoretical Result:

- An integral energy minimization problem can be reduced to a differential equation.
- We look at energy functions of a specific form:

$$f : [a, b] \rightarrow \mathbb{R}$$

$$E(f) = \int_a^b F(x, f(x), f'(x)) dx$$

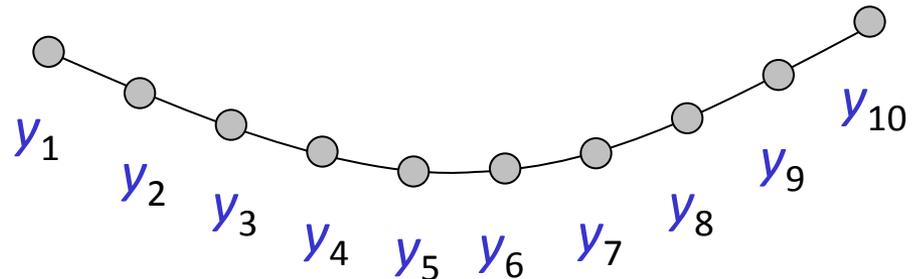

- $f$  is the unknown function
- $F$  is the energy at each point  $x$  to be integrated
- $F$  depends (at most) on the position  $x$ , the function value  $f(x)$  and the first derivative  $f'(x)$ .

# The Euler-Lagrange Equation

## Now we look for a minimum:

- Necessary condition:
- $\frac{d}{df} E(f) = 0$  (critical point)
- In order to compute this:
  - Approximate  $f$  by a polygon (finite difference approximation)
  - $f \hat{=} ((x_1, y_1), \dots, (x_n, y_n))$
  - Equally spaced:  $x_j - x_{j-1} = h$

(Can be formalized more precisely using *functional derivatives*)

# The Euler-Lagrange Equation

**Minimum condition:**

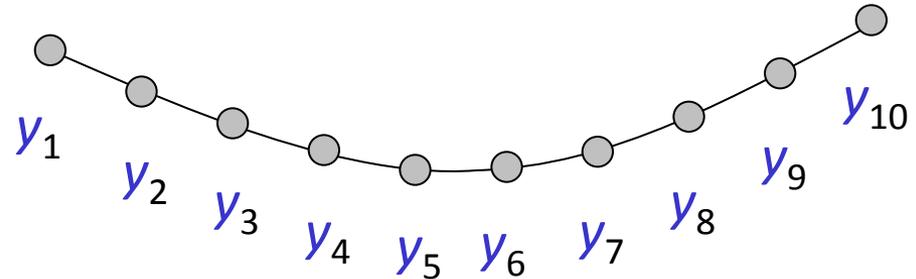

$$E(f) = \int_a^b F(x, f(x), f'(x)) dx$$

$$E(f) \approx \tilde{E}(\mathbf{y}) = \sum_{i=2}^n F\left(x_i, y_i, \frac{y_i - y_{i-1}}{h}\right)$$

$$\nabla_{\mathbf{y}} \tilde{E} = \left( \partial_{y_1}, \dots, \partial_{y_n} \right) \tilde{E}$$

$$= \sum_{i=2}^n \nabla_{\mathbf{y}} F\left(x_i, y_i, \frac{y_i - y_{i-1}}{h}\right)$$

$$= \sum_{i=2}^n \left[ \partial_2 F\left(x_i, y_i, \frac{y_i - y_{i-1}}{h}\right) \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ \vdots \\ 0 \end{pmatrix} + \partial_3 \frac{1}{h} F\left(x_i, y_i, \frac{y_i - y_{i-1}}{h}\right) \begin{pmatrix} 0 \\ \vdots \\ -1 \\ 1 \\ \vdots \\ 0 \end{pmatrix} \right]$$

# The Euler-Lagrange Equation

**Minimum condition:**

$$\nabla_{\mathbf{y}} \tilde{E} = \sum_{i=2}^n \left[ \partial_2 F \left( x_i, y_i, \frac{y_i - y_{i-1}}{h} \right) \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ \vdots \\ 0 \end{pmatrix} + \partial_3 \frac{1}{h} F \left( x_i, y_i, \frac{y_i - y_{i-1}}{h} \right) \begin{pmatrix} 0 \\ \vdots \\ -1 \\ 1 \\ \vdots \\ 0 \end{pmatrix} \right]$$

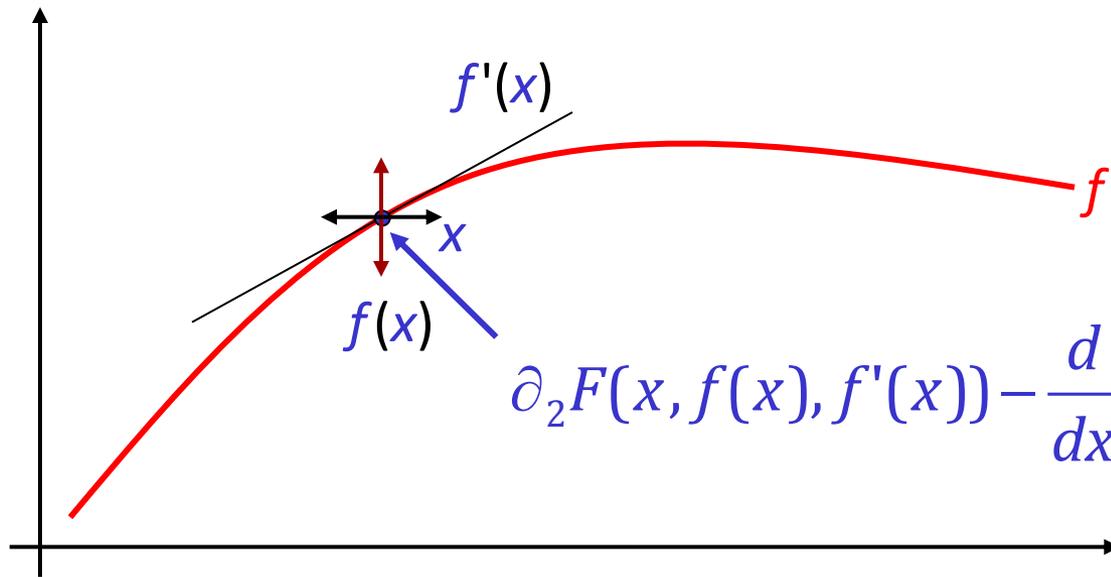

*i*th entry:

$$\partial_{y_i} \tilde{E} = \partial_2 F \left( x_i, y_i, \frac{y_i - y_{i-1}}{h} \right) - \frac{1}{h} \left( \partial_3 F \left( x_i, y_i, \frac{y_{i+1} - y_i}{h} \right) - \partial_3 F \left( x_i, y_i, \frac{y_i - y_{i-1}}{h} \right) \right)$$

Letting  $h \rightarrow 0$ , we obtain the continuous Euler-Lagrange differential equation:

$$\partial_2 F(x, f(x), f'(x)) - \frac{d}{dx} \partial_3 F(x, f(x), f'(x)) = 0$$

# The Euler-Lagrange Equation

$$\partial_2 F(x, f(x), f'(x)) - \frac{d}{dx} \partial_3 F(x, f(x), f'(x)) = 0$$

(at every point  $x$ )

# Example

## Example: Harmonic Energy

$$E(f) = \int_a^b \left( \frac{d}{dx} f(x) \right)^2 dx$$

$$F(x, f(x), f'(x)) = f'(x)^2$$

$$\partial_2 F(x, f(x), f'(x)) - \frac{d}{dx} \partial_3 F(x, f(x), f'(x)) = 0$$

$$\Leftrightarrow 0 - \frac{d}{dx} \partial_{f'(x)} (f'(x))^2 = 0$$

$$\Leftrightarrow 0 - \frac{d}{dx} 2 \frac{d}{dx} f(x) = 0$$

$$\Leftrightarrow \frac{d^2}{dx^2} f(x) = 0$$

# Generalizations

## Multi-dimensional version:

$$f : \mathbb{R}^d \supseteq \Omega \rightarrow \mathbb{R}$$

$$E(f) = \int_{\Omega} F(x_1, \dots, x_d, f(\mathbf{x}), \partial_{x_1} f(\mathbf{x}), \dots, \partial_{x_d} f(\mathbf{x})) dx_1 \dots dx_d$$

Necessary condition for extremum:

$$\frac{\partial E}{\partial f(\mathbf{x})} - \sum_{i=1}^d \frac{d}{dx_i} \frac{\partial E}{\partial f_{x_i}} = 0$$

$$f_{x_i} := \frac{\partial}{\partial x_i} f(\mathbf{x})$$

This is a *partial differential equation (PDE)*.

# Example

**Example:** General Harmonic energy

$$E^{(harmonic)}(f) = \int_{\Omega} (\nabla f(\mathbf{x}))^2 d\mathbf{x}$$

Euler Lagrange equation:

$$\Delta f(\mathbf{x}) = \left( \frac{\partial^2}{\partial x_1^2} f(\mathbf{x}) + \dots + \frac{\partial^2}{\partial x_d^2} f(\mathbf{x}) \right) = 0$$

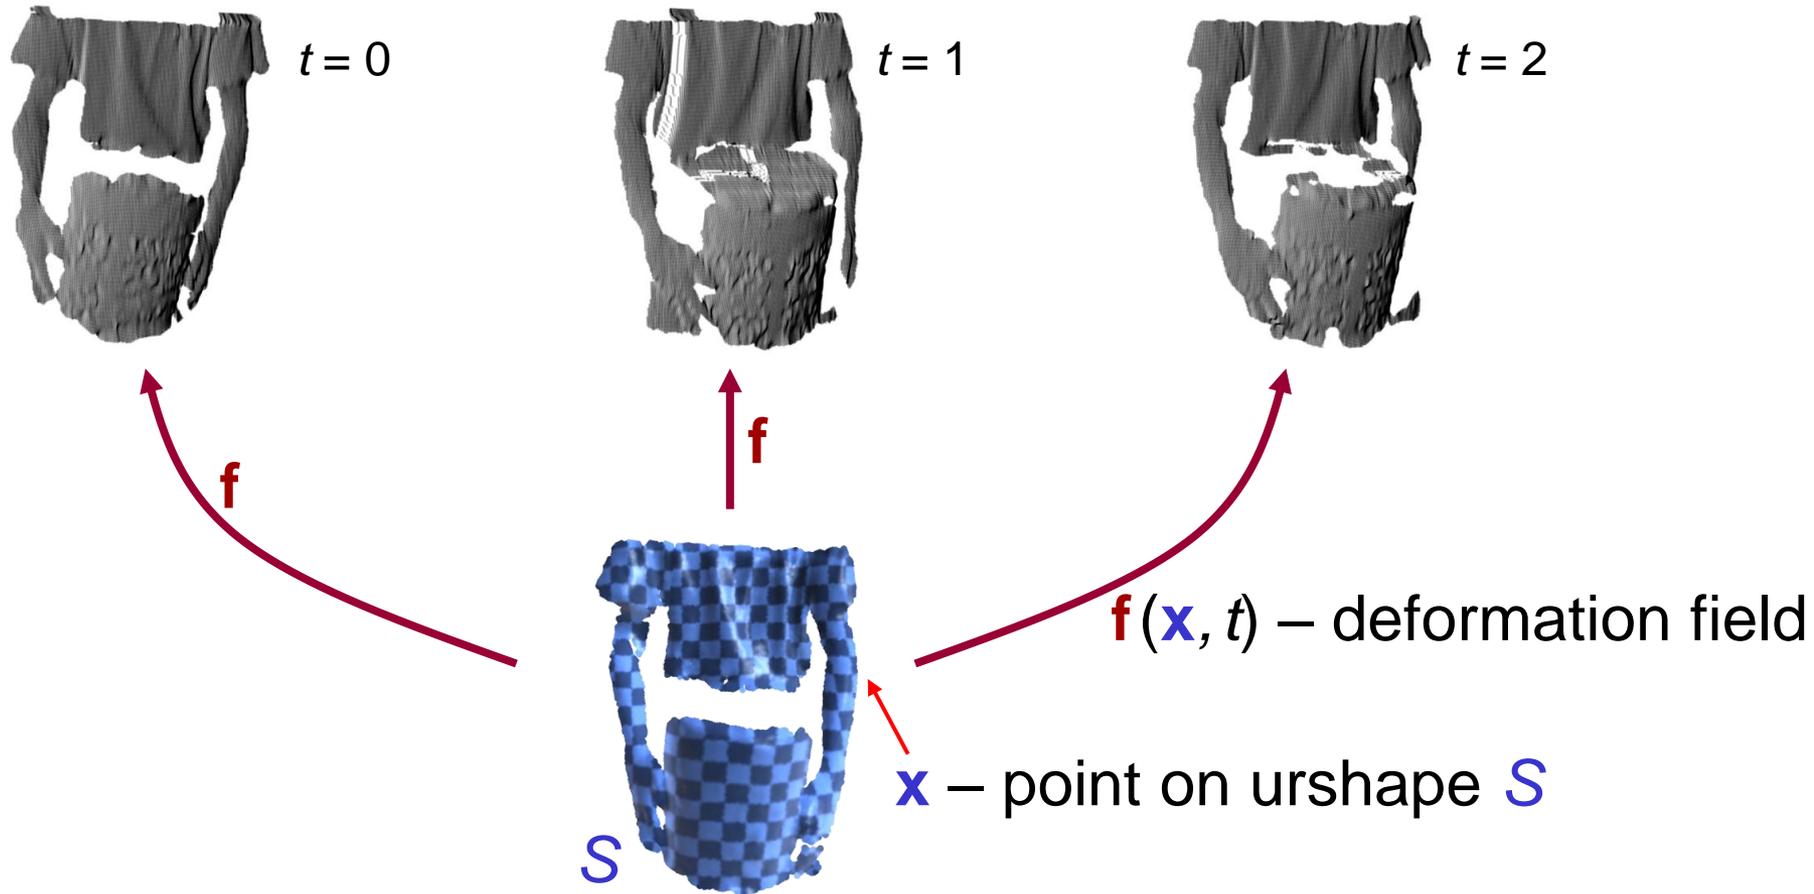

# Summary

## Euler Lagrange Equation:

- Converts integral minimization problem into ODE or PDE.
- Gives a necessary, but not sufficient condition for extremum (critical “point”, read: function  $f$ )
- Application:
  - From a numerical point of view, this does not buy us much.
    - We can usually directly optimize the integral expression.
    - Similarly complex to compute (boundary value problem for a PDE vs. variational problem).
  - Analytical tool
    - Helps understanding the minimizer functions.

# Animation Reconstruction

# Variational Animation Modeling

# Variational Framework

$$E(\mathbf{f}) = \underbrace{E_{match}(\mathbf{f})}_{\text{constraints}} + \underbrace{(E_{rigid} + E_{volume} + E_{accel} + E_{velocity})}_{\text{deformation}}(\mathbf{f})$$

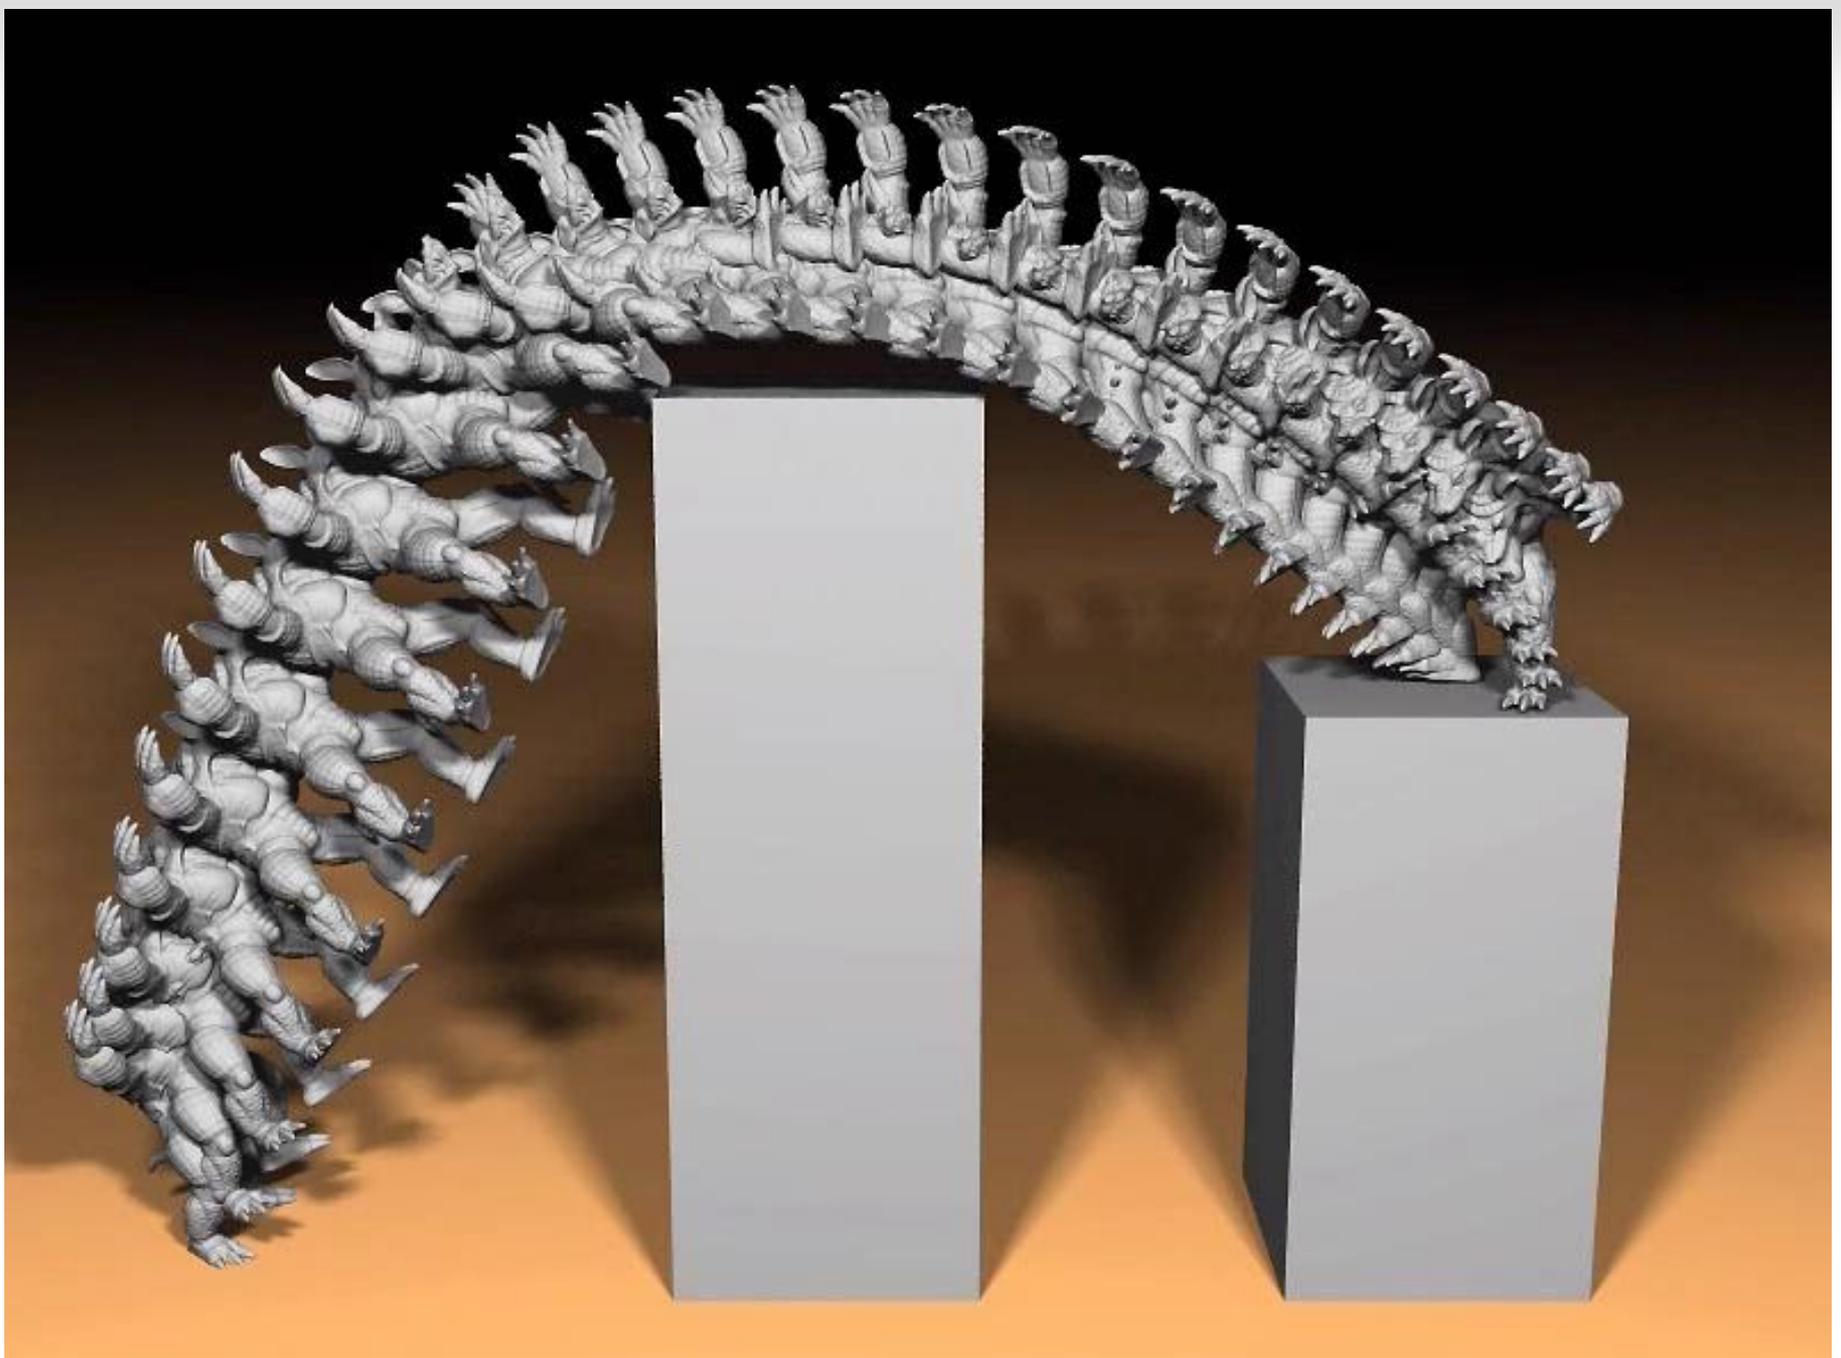

$$E_{match}(\mathbf{f}) = \sum_{t=1}^T \sum_{i=1}^{n_t} \text{dist}(d_i, f(S))^2$$

$$E_{rigid}(\mathbf{f}) = \int_{V(S)} \omega_{rigid}(x) \left\| \nabla_x \mathbf{f}(\mathbf{x}, t)^T \nabla_x \mathbf{f}(\mathbf{x}, t) - \mathbf{I} \right\|_F^2 dx$$

$$E_{volume}(\mathbf{f}) = \int_{V(S)} \omega_{vol}(x) \left( \left| \nabla_x \mathbf{f}(\mathbf{x}, t) \right| - 1 \right)^2 dx$$

$$E_{accel}(\mathbf{f}) = \int_S \omega_{acc}(x) \left( \frac{\partial^2}{\partial t^2} \mathbf{f}(\mathbf{x}, t) \right)^2 dx$$

$$E_{velocity}(\mathbf{f}) = \int_S \omega_{velocity}(x) \left( \frac{\partial}{\partial t} \mathbf{f}(\mathbf{x}, t) \right)^2 dx$$
